

## Lists

['Demo']

## Working with Lists

```
>>> digits = [1, 8, 2, 8]          >>> digits = [2//2, 2+2+2+2, 2, 2*2*2]
The number of elements
>>> len(digits)
4
An element selected by its index
>>> digits[3]
8          >>> getitem(digits, 3)
8
Concatenation and repetition
>>> [2, 7] + digits * 2          >>> add([2, 7], mul(digits, 2))
[2, 7, 1, 8, 2, 8, 1, 8, 2, 8]  [2, 7, 1, 8, 2, 8, 1, 8, 2, 8]
Nested Lists
>>> pairs = [[10, 20], [30, 40]]
>>> pairs[1]
[30, 40]
>>> pairs[1][0]
30
```

## Containers

## Containers

Built-in operators for testing whether an element appears in a compound value

```
>>> digits = [1, 8, 2, 8]
>>> 1 in digits
True
>>> 8 in digits
True
>>> 5 not in digits
True
>>> not(5 in digits)
True
```

(Demo)

## For Statements

(Demo)

## Sequence Iteration

```
def count(s, value):
    total = 0
    for element in s:
        Name bound in the first frame
        of the current environment
        (not a new frame)
        if element == value:
            total = total + 1
    return total
```

## For Statement Execution Procedure

```
for <name> in <expression>:
    <suite>
```

1. Evaluate the header <expression>, which must yield an iterable value (a sequence)
2. For each element in that sequence, in order:
  - A. Bind <name> to that element in the current frame
  - B. Execute the <suite>

## Sequence Unpacking in For Statements

```
>>> pairs = [[1, 2], [2, 2], [3, 2], [4, 4]]
>>> same_count = 0
A sequence of fixed-length sequences
A name for each element in a fixed-length sequence
Each name is bound to a value, as in multiple assignment
>>> for (x, y) in pairs:
...     if x == y:
...         same_count = same_count + 1
>>> same_count
2
```

## Ranges

## The Range Type

A range is a sequence of consecutive integers.\*

..., -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, ...

range(-2, 2)

Length: ending value - starting value

Element selection: starting value + index

(Demo)

```
>>> list(range(-2, 2))
[-2, -1, 0, 1]
```

List constructor

```
>>> list(range(4))
[0, 1, 2, 3]
```

Range with a 0 starting value

\* Ranges can actually represent more general integer sequences.

## List Comprehensions

```
>>> letters = ['a', 'b', 'c', 'd', 'e', 'f', 'm', 'n', 'o', 'p']
>>> [letters[i] for i in [3, 4, 6, 8]]
['d', 'e', 'm', 'o']
```

## List Comprehensions

```
[<map exp> for <name> in <iter exp> if <filter exp>]
```

Short version: [`<map exp> for <name> in <iter exp>`]

A combined expression that evaluates to a list using this evaluation procedure:

1. Add a new frame with the current frame as its parent
2. Create an empty *result* list that is the value of the expression
3. For each element in the iterable value of `<iter exp>`:
  - A. Bind `<name>` to that element in the new frame from step 1
  - B. If `<filter exp>` evaluates to a true value, then add the value of `<map exp>` to the result list

## Strings

### Strings are an Abstraction

Representing data:

```
'200' '1.2e-5' 'False' '[1, 2]'
```

Representing language:

```
"""And, as imagination bodies forth
The forms of things unknown, the poet's pen
Turns them to shapes, and gives to airy nothing
A local habitation and a name.
"""
```

Representing programs:

```
'curry = lambda f: lambda x: lambda y: f(x, y)'
```

(Demo)

### String Literals Have Three Forms

```
>>> 'I am string!'
'I am string!'

>>> "I've got an apostrophe"
"I've got an apostrophe"

>>> '您好'
'您好'

>>> """The Zen of Python
claims, Readability counts.
Read more: import this."""
'The Zen of Python\nclaims, Readability counts.\nRead more: import this.'
```

Single-quoted and double-quoted strings are equivalent

A backslash "escapes" the following character

"Line feed" character represents a new line

## Dictionaries

### Limitations on Dictionaries

Dictionaries are **unordered** collections of key-value pairs

Dictionary keys do have two restrictions:

- A key of a dictionary **cannot be** a list or a dictionary (or any *mutable type*)
- Two **keys cannot be equal**; There can be at most one value for a given key

This first restriction is tied to Python's underlying implementation of dictionaries

The second restriction is part of the dictionary abstraction

If you want to associate multiple values with a key, store them all in a sequence value

```
{'Dem': 0}
```

## Data Abstraction

## Data Abstraction

- Compound values combine other values together
  - A date: a year, a month, and a day
  - A geographic position: latitude and longitude
- Data abstraction lets us manipulate compound values as units
- Isolate two parts of any program that uses data:
  - How data are represented (as parts)
  - How data are manipulated (as units)
- Data abstraction: A methodology by which functions enforce an abstraction barrier between **representation** and **use**

All Programmers Great Programmers

## Rational Numbers

$$\frac{\text{numerator}}{\text{denominator}}$$

Exact representation of fractions

A pair of integers

As soon as division occurs, the exact representation may be lost! (Demo)

Assume we can compose and decompose rational numbers:

## Rational Number Arithmetic

$$\frac{3}{2} * \frac{3}{5} = \frac{9}{10}$$

$$\frac{3}{2} + \frac{3}{5} = \frac{21}{10}$$

Example

$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*ny}{dx*dy}$$
  

$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*dy + ny*dx}{dx*dy}$$

General Form

## Rational Number Arithmetic Implementation

```

def mul_rational(x, y):
    return rational(numer(x) * numer(y),
                   denom(x) * denom(y))
    Constructor Selectors
    
```

$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*ny}{dx*dy}$$

```

def add_rational(x, y):
    nx, dx = numer(x), denom(x)
    ny, dy = numer(y), denom(y)
    return rational(nx * dy + ny * dx, dx * dy)
    
```

$$\frac{nx}{dx} + \frac{ny}{dy} = \frac{nx*dy + ny*dx}{dx*dy}$$

```

def print_rational(x):
    print(numer(x), '/', denom(x))
    
```

```

def rational_are_equal(x, y):
    return numer(x) * denom(y) == numer(y) * denom(x)
    
```

- rational(n, d) returns a rational number x
- numer(x) returns the numerator of x
- denom(x) returns the denominator of x

These functions implement an abstract representation for rational numbers

Pairs

## Representing Pairs Using Lists

```

>>> pair = [1, 2]
>>> pair
[1, 2]
>>> x, y = pair
>>> x
1
>>> y
2
>>> pair[0]
1
>>> pair[1]
2
>>> from operator import getitem
>>> getitem(pair, 0)
1
>>> getitem(pair, 1)
2
    
```

A list literal:  
Comma-separated expressions in brackets

"Unpacking" a list

Element selection using the selection operator

Element selection function

## Representing Rational Numbers

```

def rational(n, d):
    """Construct a rational number that represents N/D."""
    return [n, d]
    Construct a list
    
```

```

def numer(x):
    """Return the numerator of rational number X."""
    return x[0]
    
```

```

def denom(x):
    """Return the denominator of rational number X."""
    return x[1]
    Select item from a list
    
```

(Demo)

## Reducing to Lowest Terms

Example:

$$\frac{3}{2} * \frac{5}{3} = \frac{5}{2}$$

$$\frac{2}{5} + \frac{1}{18} = \frac{1}{2}$$

$$\frac{15}{6} * \frac{1/3}{1/3} = \frac{5}{2}$$

$$\frac{25}{50} * \frac{1/25}{1/25} = \frac{1}{2}$$

```

from fractions import gcd
def rational(n, d):
    """Construct a rational that represents n/d in lowest terms."""
    g = gcd(n, d)
    return [n/g, d/g]
    
```

Greatest common divisor

(Demo)

Abstraction Barriers

## Abstraction Barriers

Parts of the program that...	Treat rationals as...	Using...
Use rational numbers to perform computation	whole data values	add_rational, mul_rational, rationals_are_equal, print_rational
Create rationals or implement rational operations	numerators and denominators	rational, numer, denom
Implement selectors and constructor for rationals	two-element lists	list literals and element selection

*Implementation of lists*

## Violating Abstraction Barriers

```

add_rational( [1, 2], [1, 4] )

```

Does not use constructors (pointing to [1, 2])  
Twice! (pointing to both [1, 2] and [1, 4])

```

def divide_rational(x, y):
    return [ x[0] * y[1], x[1] * y[0] ]

```

No selectors! (pointing to x[0] and y[1])  
And no constructor! (pointing to the list literals)

Data Representations

## What are Data?

- We need to guarantee that constructor and selector functions work together to specify the right behavior
- Behavior condition: If we construct rational number x from numerator n and denominator d, then numer(x)/denom(x) must equal n/d
- Data abstraction uses selectors and constructors to define behavior
- If behavior conditions are met, then the representation is valid

You can recognize an abstract data representation by its behavior

(Demo)

## Rationals Implemented as Functions

```

def rational(n, d):
    def select(name):
        if name == 'n':
            return n
        elif name == 'd':
            return d
        return select
    return select

```

This function represents a rational number (pointing to the select function)

Constructor is a higher-order function (pointing to the return select line)

```

def numer(x):
    return x('n')

```

Selector calls x (pointing to the return x('n') line)

```

def denom(x):
    return x('d')

```

Global frame

- rational: func rational(n, d) (parent=Global)
- numer: func numer(x) (parent=Global)
- denom: func denom(x) (parent=Global)
- x: func select(name) (parent=r1)

r1: rational (parent=Global)

- n: 3
- d: 8
- select: func
- Return: value

r2: numer (parent=Global)

- x: func
- Return: 3
- value: value

r3: select (parent=r1)

- name: 'n'
- Return: 3
- value: value

x = rational(3, 8)  
numer(x)

Dictionaries

{'Dem': 0}

## Limitations on Dictionaries

Dictionaries are **unordered** collections of key-value pairs

Dictionary keys do have two restrictions:

- A key of a dictionary **cannot be** a list or a dictionary (or any mutable type)
- Two **keys cannot be equal**; There can be at most one value for a given key

This first restriction is tied to Python's underlying implementation of dictionaries

The second restriction is part of the dictionary abstraction

If you want to associate multiple values with a key, store them all in a sequence value
