CS61B Lecture #33

**Today's Readings:**   Graph Structures: *DSIJ, Chapter 12*

Why Graphs?

- For expressing non-hierarchically related items

- Examples:

  - Networks: pipelines, roads, assignment problems
  - Representing processes: flow charts, Markov models
  - Representing partial orderings: PERT charts, makefiles

Some Terminology

- A *graph* consists of

    - A set of *nodes* (aka *vertices*)
    - A set of *edges:* pairs of nodes.
    - Nodes with an edge between are *adjacent*.
    - Depending on problem, nodes or edges may have *labels* (or *weights*)

- Typically call node set $V = \{v_0, \ldots\}$, and edge set E.

- If the edges have an order (first, second), they are *directed edges,* and we have a *directed graph (digraph),* otherwise an *undirected graph*.

- Edges are *incident* to their nodes.

- Directed edges *exit* one node and *enter* the next.

- A *cycle* is a path without repeated edges leading from a node back to itself (following arrows if directed).

- A graph is *cyclic* if it has a cycle, else *acyclic*. Abbreviation: Directed Acyclic Graph—*DAG*.

Some Pictures

Directed   Undirected

Acyclic:

Cyclic:

With Edge Labels:
Trees are Graphs

- A graph is *connected* if there is a (possibly directed) path between every pair of nodes.

- That is, if one node of the pair is *reachable* from the other.

- A DAG is a (rooted) tree iff connected, and every node but the root has exactly one parent.

- A connected, acyclic, undirected graph is also called a *free tree.* Free: we're free to pick the root; e.g.,
Examples of Use

- Edge = Connecting road, with length.

Detroit —200— Chicago
- Edge = Must be completed before; Node label = time to complete.
Eat 1 hr → Sleep 8 hrs

- Edge = Begat
Martin → George

More Examples

- Edge = some relationship

- Edge = next state might be (with probability)

- Edge = next state in state machine, label is triggering input. (Start at s. Being in state 4 means "there is a substring '001' somewhere in the input".)

Representation

- Often useful to number the nodes, and use the numbers in edges.

- *Edge list representation:* each node contains some kind of list (e.g., linked list or array) of its successors (and possibly predecessors).
- *Edge sets:* Collection of all edges. For graph above:

$$\{(1,2), (1,3), (2,3)\}$$

- *Adjacency matrix:* Represent connection with matrix entry:

$$\begin{array}{c c}
& \begin{array}{c c c} 1 & 2 & 3 \end{array} \\
\begin{array}{c} 1 \\ 2 \\ 3 \end{array} &
\begin{bmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}
\end{array}$$

Traversing a Graph

- Many algorithms on graphs depend on traversing all or some nodes.

- Can't quite use recursion because of cycles.

- Even in acyclic graphs, can get combinatorial explosions:

  Treat 0 as the root and do recursive traversal down the two edges out of each node: $\Theta(2^N)$ operations!

- So typically try to visit each node constant # of times (e.g., once).

Recursive Depth-First Traversal of a Graph

- Can fix looping and combinatorial problems using the "bread-crumb" method used in earlier lectures for a maze.

- That is, *mark* nodes as we traverse them and don't traverse previously marked nodes.

- Makes sense to talk about *preorder* and *postorder*, as for trees.

```
void preorderTraverse(Graph G, Node v)
{
    if (v is unmarked) {
      mark(v);
      visit v;
      for (Edge(v, w) ∈ G)
        traverse(G, w);
    }
}
```

```
void postorderTraverse(Graph G, Node v)
{
    if (v is unmarked) {
      mark(v);
      for (Edge(v, w) ∈ G)
        traverse(G, w);
      visit v;
    }
}
```

Recursive Depth-First Traversal of a Graph (II)

- We are often interested in traversing *all* nodes of a graph, not just those reachable from one node.

- So we can repeat the procedure as long as there are unmarked nodes.

```
void preorderTraverse(Graph G) {
    for (v ∈ nodes of G) {
        preorderTraverse(G, v);
    }
}

void postorderTraverse(Graph G) {
    for (v ∈ nodes of G) {
        postorderTraverse(G, v);
    }
}
```

Topological Sorting

Problem: Given a DAG, find a linear order of nodes consistent with the edges.

- That is, order the nodes $v_0,\ v_1,\ \ldots$ such that v_k is never reachable from $v_{k'}$ if $k' > k$.

- Gmake does this. Also PERT charts.

A	C	C
C	A	F
		G
B	F	
D	D	A
F	B	B
E	G	D
G	E	E
		H
H	H	
Sorting and Depth First Search

- **Observation**: Suppose we *reverse the links* on our graph.

- If we do a recursive DFS on the reverse graph, starting from node H, for example, we will find all nodes that must come *before* H.

- When the search reaches a node in the reversed graph and there are no successors, we know that it is safe to put that node first.

- In general, a *postorder* traversal of the reversed graph visits nodes only after all predecessors have been visited.
Numbers show post-order traversal order starting from G: everything that must come before G.

General Graph Traversal Algorithm

```
COLLECTION_OF_VERTICES fringe;

fringe = INITIAL_COLLECTION;
while (!fringe.isEmpty()) {
  Vertex v = fringe.REMOVE_HIGHEST_PRIORITY_ITEM();

  if (!MARKED(v)) {
    MARK(v);
    VISIT(v);
    For each edge(v,w) {
      if (NEEDS_PROCESSING(w))
        Add w to fringe;
    }
  }
}
```

Replace *COLLECTION_OF_VERTICES*, *INITIAL_COLLECTION*, etc.
with various types, expressions, or methods to different graph algo-
rithms.

# Example: Depth-First Traversal

Problem: Visit every node reachable from v once, visiting nodes further from start first.

```
Stack<Vertex> fringe;

fringe = stack containing {v};
while (!fringe.isEmpty()) {
  Vertex v = fringe.pop();

  if (!marked(v)) {
    mark(v);
    VISIT(v);
    For each edge(v,w) {
      if (!marked(w))
        fringe.push(w);
    }
  }
}
```
# Depth-First Traversal Illustrated

Shortest Paths: Dijkstra's Algorithm

Problem: Given a graph (directed or undirected) with non-negative edge weights, compute shortest paths from given source node, s, to all nodes.

- "Shortest" = sum of weights along path is smallest.

- For each node, keep estimated distance from s, ...

- ...and of preceding node in shortest path from s.

```
PriorityQueue<Vertex> fringe;
For each node v { v.dist() = ∞; v.back() = null; }
s.dist() = 0;
fringe = priority queue ordered by smallest .dist();
add all vertices to fringe;
while (!fringe.isEmpty()) {
  Vertex v = fringe.removeFirst();

  For each edge(v,w) {
    if (v.dist() + weight(v,w) < w.dist())
      { w.dist() = v.dist() + weight(v,w); w.back() = v; }
  }
}
```

Example

Final result:

Shortest-path tree ------►

X|d processed node at distance d

Y|d node in fringe at distance d
