What is the dynamic type of `f` in `A`?

**Choices**  
a. A.f  
b. B.f  
c. Some kind of error

### Answer to Puzzle

When `h` is called from `main`, `h` prints `A.f`, because `h` is called on `aB`, whose dynamic type is `B`.  
When `h` is called from `main`, `h` prints `A.f`. Since `g` is inherited by `B`, we execute the code for `A.g()`.  
When `h` is called from `main`, `h` prints `A.f`. Now `this` contains the value of `h`'s argument, whose dynamic type is `B`. Therefore, we execute the definition of `B.g()`.  
When `h` is called from `main`, `h` prints `A.f`. In other words, static type is ignored in figuring out how to call `g`.  
When `h` is called from `main`, we see `A.f`; selection of `f` still depends on dynamic type of `this`. Same for overriding `g` in `B`.  
When `h` is called from `main`, `h` would print `A.f` because then selection of `f` is based on static type of `this`, which is `A`.  
When `h` is called from `main`, `h` would print `A.f`. If `g` were defined in `A`, we'd see `A.f`.

### Review: A Puzzle

```
System.out.println("A.f");  
/* or this.f() */  
  
class B extends A {  
    static void f() {  
        System.out.println("B.f");  
    }  
}
```

```
class C {  
    static void main(String[] args) {  
        B aB = new B();  
        h(aB);  
    }  
  
    static void h(A x) { x.g(); }  
}
```

**Choices**  
a. A.f  
b. B.f  
c. Some kind of error

## Example: Designing a Class

Write a class that represents histograms, like this one:

What do we need from it? At least:

Methods and limits.

Counts of values.

Limits of values.

Numbers of buckets and other initial parameters.

6:16 2021

CS61B: Lecture #10 14

## Histogram Specification and Use

```
of floating-point values */
Histogram {
  of buckets in THIS. */

  of bucket #K. Pre: 0<=K<size(). */
  k);

  s in bucket #K. Pre: 0<=K<size(). */
  k);

  the histogram. */
  e val);

am(Histogram H, Scanner in) {
  void printHistogram(Histogram H) {
    for (int i = 0; i < H.size(); i += 1)
      System.out.printf
        (">=%5.2f | %4d\n",
         H.low(i), H.count(i));
  }
}
```

Sample output:

```
>= 0.00 | 10
>= 10.25 | 80
>= 20.50 | 120
>= 30.75 | 50
```

6:16 2021

CS61B: Lecture #10 16

## Let's Make a Tiny Change

*priori* bounds:

```
Histogram implements Histogram {
  w histogram with SIZE buckets. */
  lexHistogram(int size) {
```

needs to change?

How do you do this? Profoundly changes implementation.

How do you make `printHistogram` and `fillHistogram` still work with

the power of *separation of concerns*.

6:16 2021

CS61B: Lecture #10 18

## Answer to Puzzle

When `va C` prints `_B.f_`, because

`lls h` and passes it `aB`, whose dynamic type is `B`.

`g()`. Since `g` is inherited by `B`, we execute the code for `A`.

`is.f()`. Now `this` contains the value of `h`'s argument, whose dynamic type is `B`. Therefore, we execute the definition of `in B`.

`> f`, in other words, static type is ignored in figuring out the method to call.

Therefore, we see `_B.f_`; selection of `f` still depends on dynamic type `this`. Same for overriding `g` in `B`.

Therefore, would print `_A.f_` because then selection of `f` is based on static type of `this`, which is `A`.

Therefore, if `f` is defined in `A`, we'd see a compile-time error

6:16 2021

CS61B: Lecture #10 13

## Specification Seen by Clients

What the programs (a module, class, program, etc.) are the programs or clients that use that module's exported definitions.

The important notion is that exported definitions are designated **public**. Clients are intended to rely on *specifications*, (aka APIs) not code.

**Specification:** method and constructor headers—syntax and semantics.

**Specification:** what they do. No formal notation, so use natural language.

A specification is a *contract*.

A client must satisfy (*preconditions*, marked "Pre:" in the code).

Results (*postconditions*).

Use these to be *all the client needs!*

How do we communicate errors, specifically failure to meet preconditions?

6:16 2021

CS61B: Lecture #10 15

## An Implementation

```
edHistogram implements Histogram {
  _low, _high; /* From constructor*/
  _count; /* Value counts */

  program with SIZE buckets of values >= LOW and < HIGH. */
  Histogram(int size, double low, double high) {

    if (size <= 0) throw new IllegalArgumentException();
    _high = high;
    int[] _count = new int[size];

    fill();
    return _count.length;
  }
  low(int k) { return _low + k*(-_high-_low)/_count.length; }
  high(int k) { return _count[k]; }

  fill(double val) {
    int i = 0;
    while (_low && val < _high)
      _count[i++] = ((val-_low)/(_high-_low) * _count.length) += 1;
  }
}
```

6:16 2021

CS61B: Lecture #10 17

## of Procedural Interface over Visible Fields

method for `count` instead of making the array `_count` / change" is transparent to clients:

to write `myHist._count[k]`, it would mean

ber of items currently in the  $k^{\text{th}}$  bucket of histogram  
hich, by the way, is stored in an array called `_count`  
that always holds the up-to-date count)."

l comment *worse than useless* to the client.

ray had been visible, after "tiny change," *every use* of  
nt program would have to change.

method for the public `count` method decreases what  
know, and (therefore) has to change.

## Implementing the Tiny Change

pre-allocate the `_count` array.

ounds, so must save arguments to `add`.

ute `_count` array "lazily" when `_count(...)` called.

ount array whenever histogram changes.

```
ogram implements Histogram {
rayList<Double> _values = new ArrayList<>();

t[] _count;

xHistogram(int size) { _size = size; _count = null; }

d add(double x) { _count = null; _values.add(x); }

count(int k) {
nt == null) { compute_count_from_values_here. }
count[k];
```
