

Lecture 7 – Introduction to MIPS
Decisions II

2014-09-15

Instructor:
Miki Lustig

EETimes article 08/07/2014
RISC-V: An open standard for SoCs. The case for an open
ISA (Krstic, Patterson, UC Berkeley).
While the likely first beachhead for RISC-V is the IoT, our ambitious goal is grander:
Just as Linux has become the standard OS for most computing devices, we
envision RISC-V becoming the standard ISA for all computing devices.

Review

- Memory is **byte**-addressable, but **lw** and **sw** access one **word** at a time.
- A pointer (used by **lw** and **sw**) is just a memory address, so we can add to it or subtract from it (using offset).
- A Decision allows us to decide what to execute at run-time rather than compile-time.
- C Decisions are made using **conditional statements** within **if**, **while**, **do while**, **for**.
- MIPS Decision making instructions are the **conditional branches**: **beq** and **bne**.
- New Instructions:

lw, **sw**, **beq**, **bne**, **j**

Loading, Storing bytes 1/2

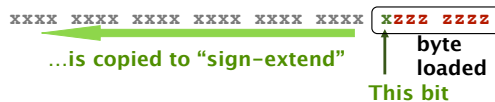

- In addition to word data transfers (**lw**, **sw**), MIPS has **byte** data transfers:
 - load byte: **lb**
 - store byte: **sb**
- same format as **lw**, **sw**
- E.g., **lb \$s0, 3(\$s1)**
 - contents of memory location with address = sum of “3” + contents of register **s1** is copied to the low byte position of register **s0**.

Loading, Storing bytes 2/2

• What do with other 24 bits in the 32 bit register?

- **lb**: sign extends to fill upper 24 bits

• Normally don't want to sign extend chars

• MIPS instruction that doesn't sign extend when loading bytes:

- load byte unsigned: **lbu**

Overflow in Arithmetic (1/2)

• Reminder: Overflow occurs when there is a “mistake” in arithmetic due to the limited precision in computers.

• Example (4-bit unsigned numbers):

$$\begin{array}{r} 15 \\ + 3 \\ \hline 18 \end{array} \qquad \begin{array}{r} 1111 \\ + 0011 \\ \hline 10010 \end{array}$$

• But we don't have room for 5-bit solution, so the solution would be 0010, which is +2, and “wrong”.

Overflow in Arithmetic (2/2)

- Some languages detect overflow (Ada), some don't (most C implementations)
- MIPS solution is 2 kinds of arithmetic instructions:
 - These **cause overflow to be detected**
 - add (add)
 - add immediate (addi)
 - subtract (sub)
 - These **do not cause overflow detection**
 - add unsigned (addu)
 - add immediate unsigned (addiu)
 - subtract unsigned (subu)
- Compiler selects appropriate arithmetic
- MIPS C compilers produce **addu, addiu, subu**

Two "Logic" Instructions

- Here are 2 more new instructions
- Shift Left: **sll \$s1, \$s2, 2** #s1=s2<<2
 - Store in \$s1 the value from \$s2 shifted 2 bits to the left (they fall off end), **inserting 0's** on right; << in C.
 - Before: 0000 0002_{hex}
0000 0000 0000 0000 0000 0000 0010_{two}
 - After: 0000 0008_{hex}
0000 0000 0000 0000 0000 0000 1000_{two}
 - What arithmetic effect does shift left have?
- Shift Right: **srl** is opposite shift; >>

Loops in C/Assembly (1/3)

- Simple loop in C; **A[]** is an array of ints

```
do { g = g + A[i];
    i = i + j;
} while (i != h);
```

- Rewrite this as:

```
Loop: g = g + A[i];
      i = i + j;
      if (i != h) goto Loop;
```

- Use this mapping:

```
g, h, i, j, &A[0]
$s1, $s2, $s3, $s4, $s5
```

Loops in C/Assembly (2/3)

- Final compiled MIPS code:

```
Loop: sll $t1, $s3, 2 # $t1 = 4*i
      addu $t1, $t1, $s5 # $t1 = addr A+4i
      lw $t1, 0($t1) # $t1 = A[i]
      addu $s1, $s1, $t1 # g = g + A[i]
      addu $s3, $s3, $s4 # i = i + j
      bne $s3, $s2, Loop # goto Loop
                          # if i != h
```

- Original code:

```
Loop: g = g + A[i];
      i = i + j;
      if (i != h) goto Loop;
```

Loops in C/Assembly (3/3)

- There are three types of loops in C:

- while
- do ... while
- for

- Each can be rewritten as either of the other two, so the method used in the previous example can be applied to these loops as well.

- Key Concept: Though there are multiple ways of writing a loop in MIPS, the key to decision-making is conditional branch

Inequalities in MIPS (1/4)

- Until now, we've only tested equalities (== and != in C). General programs need to test < and > as well.

- Introduce MIPS Inequality Instruction:

- "Set on Less Than"
- Syntax: **slt reg1, reg2, reg3**
- Meaning: **reg1 = (reg2 < reg3);**

```
if (reg2 < reg3)
    reg1 = 1;
else reg1 = 0;
```

← Same thing...

"set" means "change to 1",
"reset" means "change to 0".

Inequalities in MIPS (2/4)

•How do we use this? Compile by hand:
`if (g < h) goto Less; #g:$s0, h:$s1`

•Answer: compiled MIPS code...

```
slt $t0,$s0,$s1 # $t0 = 1 if g<h
bne $t0,$0,Less # goto Less
                # if $t0!=0
                # (if (g<h)) Less:
```

•Register \$0 always contains the value 0, so `bne` and `beq` often use it for comparison after an `slt` instruction.

 A `slt` → `bne` pair means `if(... < ...)goto...`

Inequalities in MIPS (3/4)

•Now we can implement `<`,
but how do we implement `>`, `≤` and `≥` ?

•We could add 3 more instructions, but:
•MIPS goal: **Simpler is Better**

•Can we implement `≤` in one or more instructions using just `slt` and branches?
•What about `>`?
•What about `≥`?

Inequalities in MIPS (4/4)

```
# a:$s0, b:$s1
slt $t0,$s0,$s1 # $t0 = 1 if a<b
beq $t0,$0,skip # skip if a >= b
<stuff> # do if a<b
skip:
```

Two independent variations possible:
Use `slt $t0,$s1,$s0` instead of
`slt $t0,$s0,$s1`
Use `bne` instead of `beq`

Immediates in Inequalities

•There is also an immediate version of `slt` to test against constants: `slti`
•Helpful in for loops

C if (g >= 1) goto Loop

```
M Loop: . . .
I slti $t0,$s0,1 # $t0 = 1 if
P # $s0<1 (g<1)
S beq $t0,$0,Loop # goto Loop
                # if $t0==0
                # (if (g>=1))
```

An `slt` → `beq` pair means `if(... ≥ ...)goto...`

What about unsigned numbers?

•Also **unsigned** inequality instructions:
`sltu, sltiu`

...which sets result to 1 or 0 depending on unsigned comparisons

•What is value of `$t0`, `$t1`?

(`$s0 = FFFF FFFAhex`, `$s1 = 0000 FFFAhex`)

```
slt $t0, $s0, $s1
sltu $t1, $s0, $s1
```

MIPS Signed vs. Unsigned – diff meanings!

•MIPS terms Signed/Unsigned “overloaded”:

- Do/Don't sign extend
 - (`lb`, `lbu`)
- Do/Don't overflow
 - (`add`, `addi`, `sub`, `mult`, `div`)
 - (`addu`, `addiu`, `subu`, `multu`, `divu`)
- Do signed/unsigned compare
 - (`slt`, `slti`/`sltu`, `sltiu`)

Peer Instruction

```

Loop:addi $s0 $s0      # i = i - 1
      slti $t0 $s1     # $t0 = (j < 2)
      beq  $t0 $0 Loop # goto Loop if $t0 == 0
      slt  $t0 $s1 $s0 # $t0 = (j < i)
      bne $t0 $0 Loop # goto Loop if $t0 != 0
  
```

(\$s0=i \$s1=j)

What C code properly fills in the blank in loop below?

do {i--;} while(____);

```

00000000000000000000000000000000
11111111111111111111111111111111
22222222222222222222222222222222

99999999999999999999999999999999
  
```

“And in conclusion...”

- To help the conditional branches make decisions concerning inequalities, we introduce: “Set on Less Than” called `slt, slti, sltu, sltiu`

- One can store and load (signed and unsigned) bytes as well as words with `lb, lbu`

- Unsigned add/sub don't cause overflow

- New MIPS Instructions:

```

sll, srl, lb, lbu
slt, slti, sltu, sltiu
addu, addiu, subu
  
```
