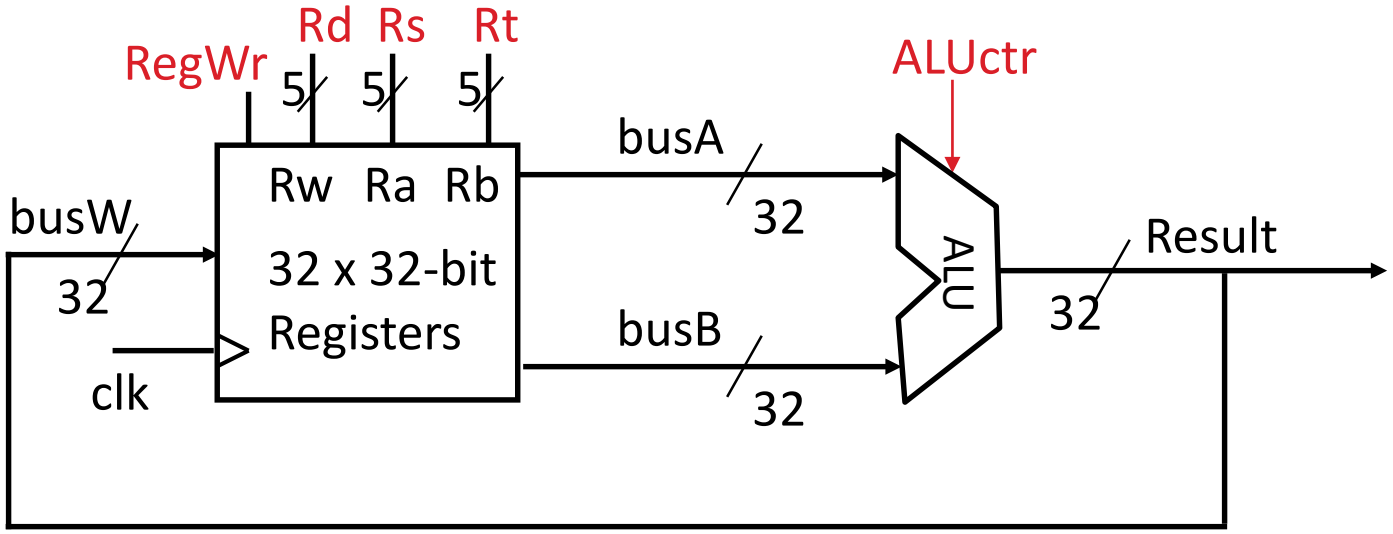
Step 3b: Add & Subtract

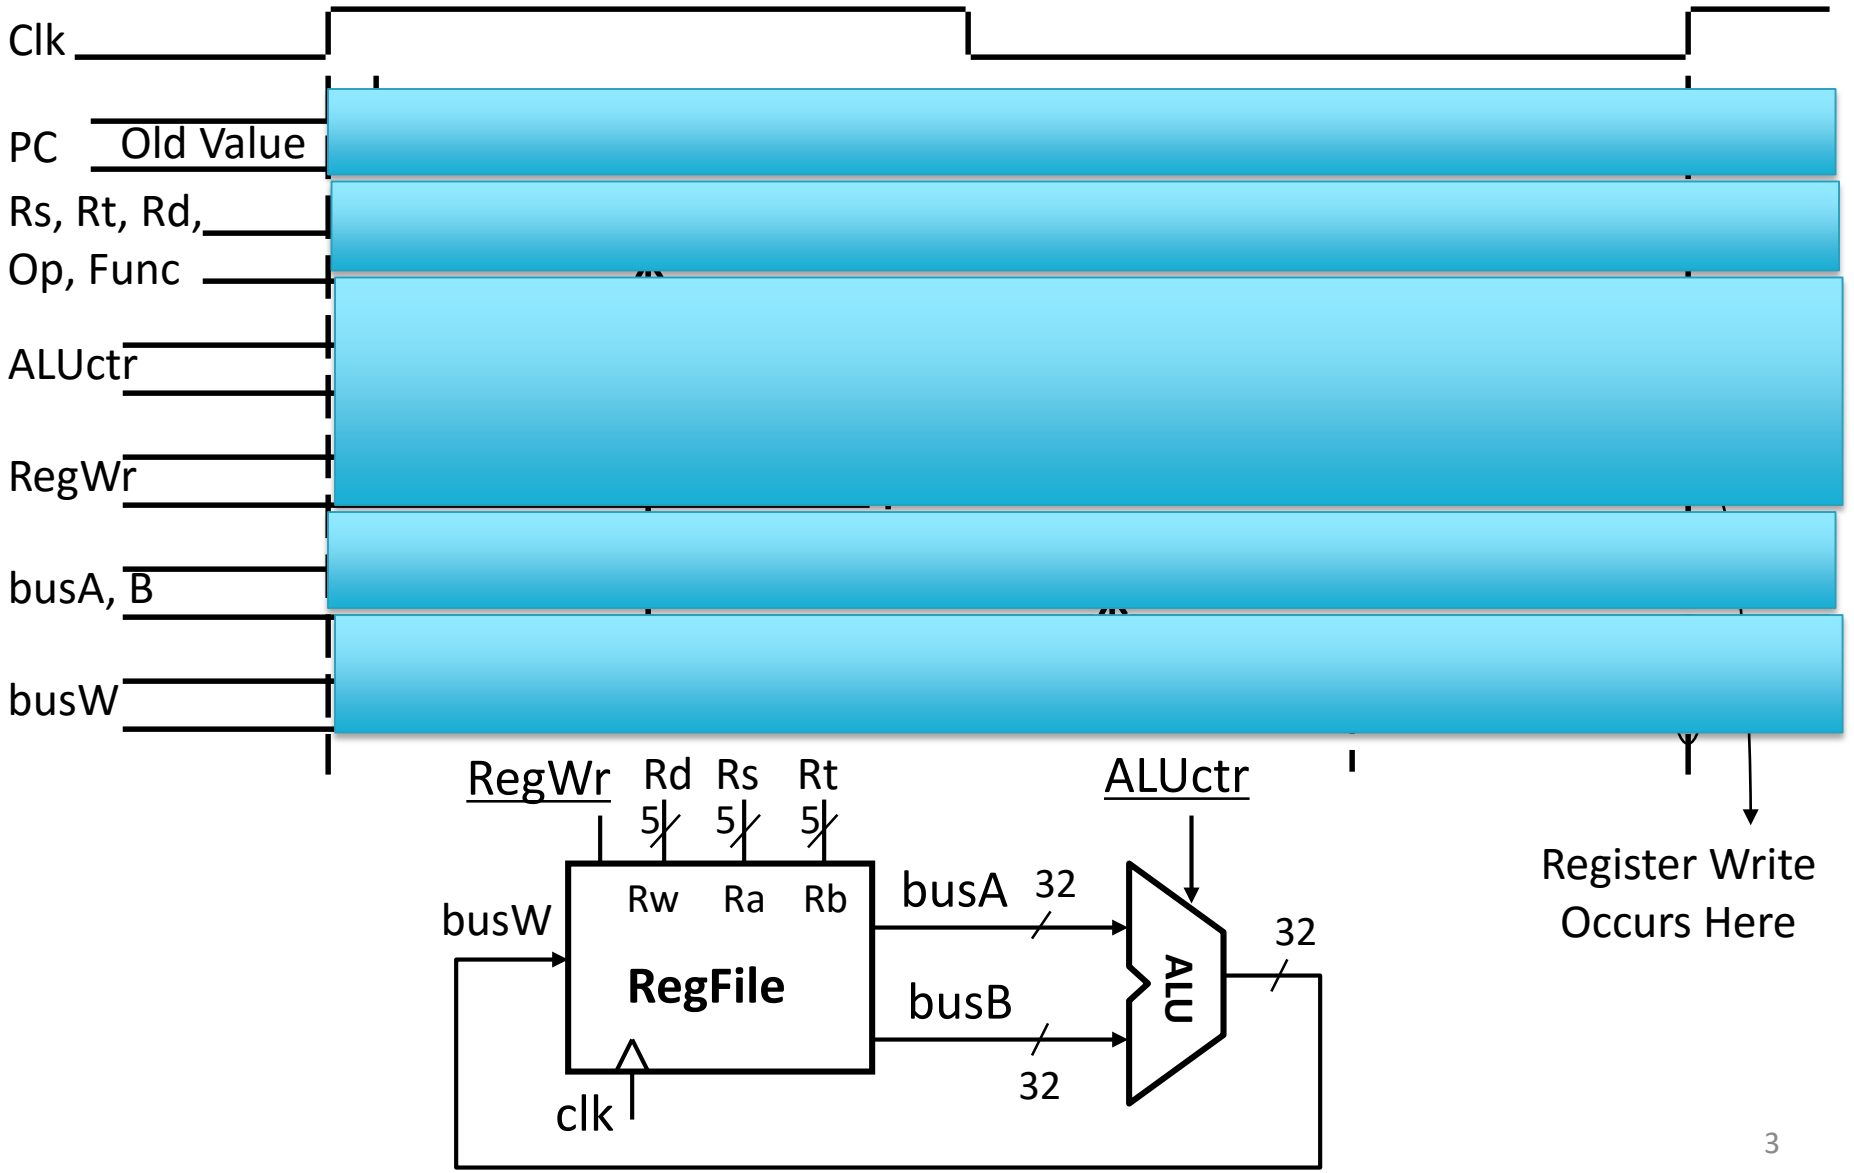
- `R[rd] = R[rs] op R[rt] (addu rd,rs,rt)`
  - Ra, Rb, and Rw come from instruction's Rs, Rt, and Rd fields

  - ALUctr and RegWr: control logic after decoding the instruction

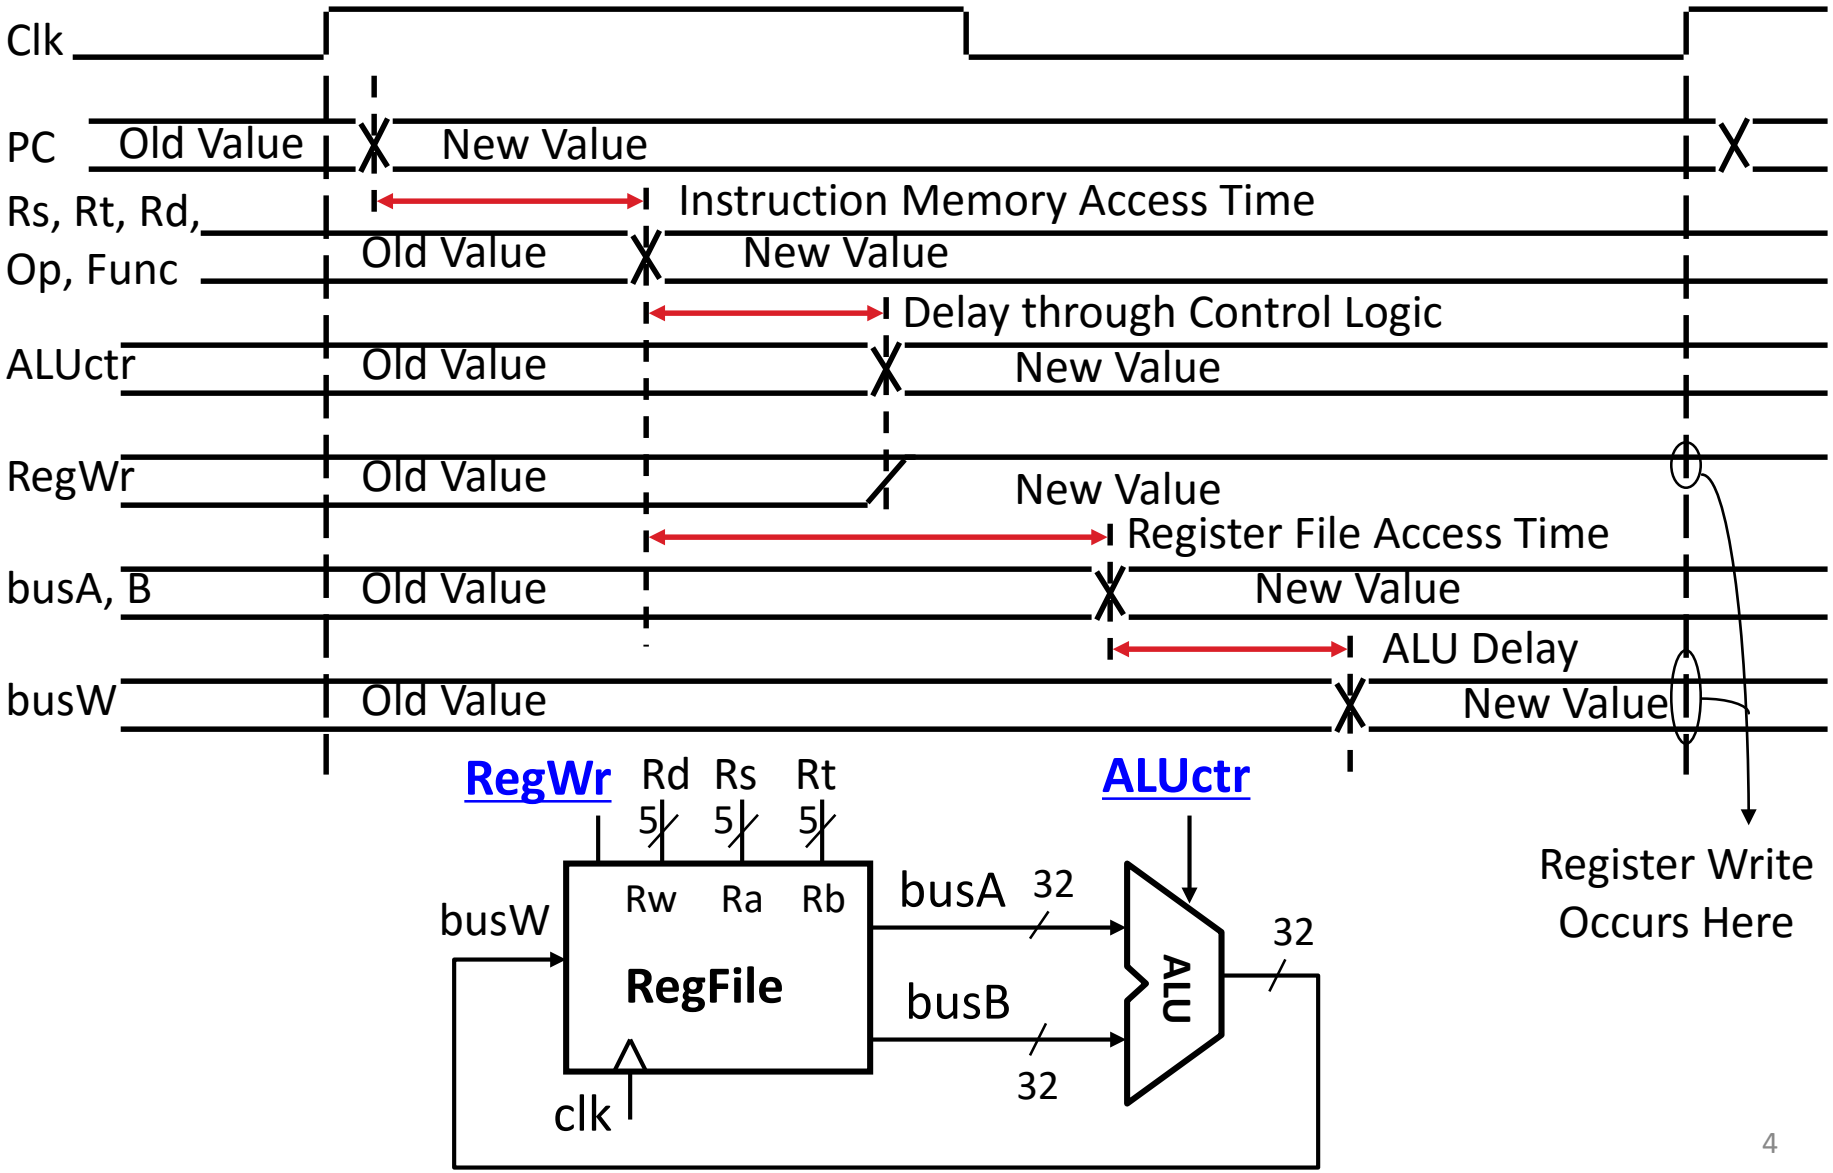


- … Already defined the register file & ALU

Register-Register Timing: One Complete Cycle (Add/Sub)

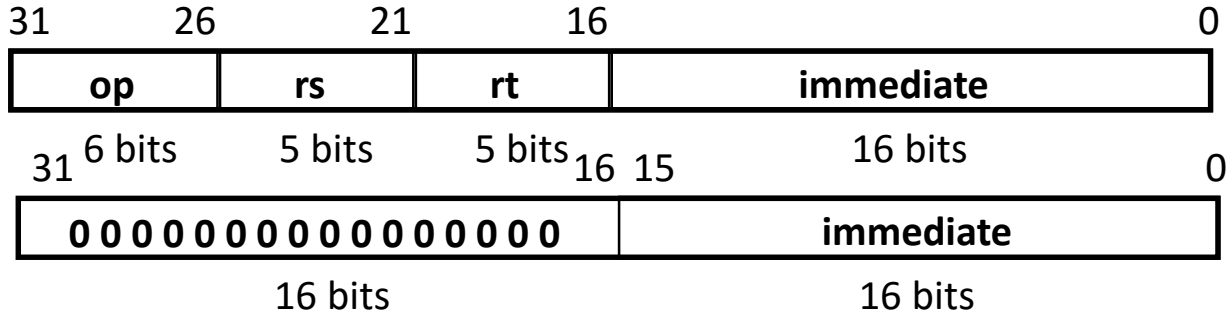


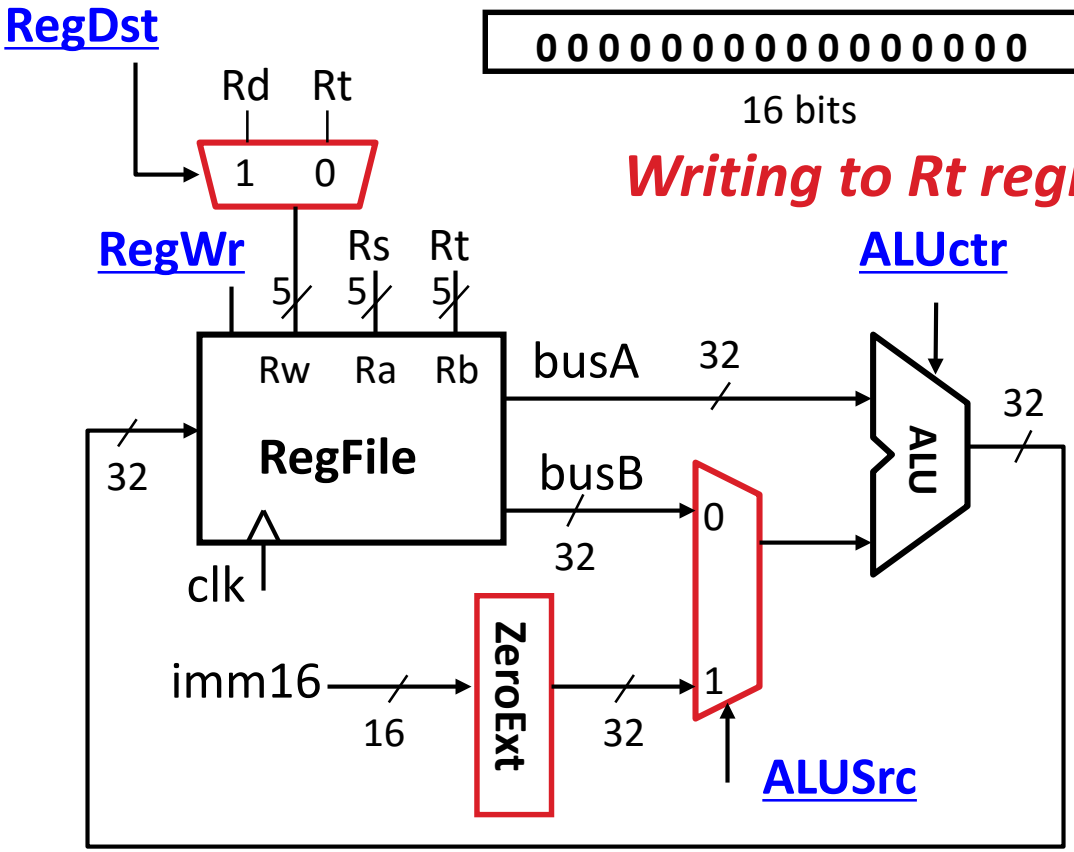
Register-Register Timing: One Complete Cycle



3c: Logical Op (or) with Immediate

- R[rt] = R[rs] op ZeroExt[imm16]



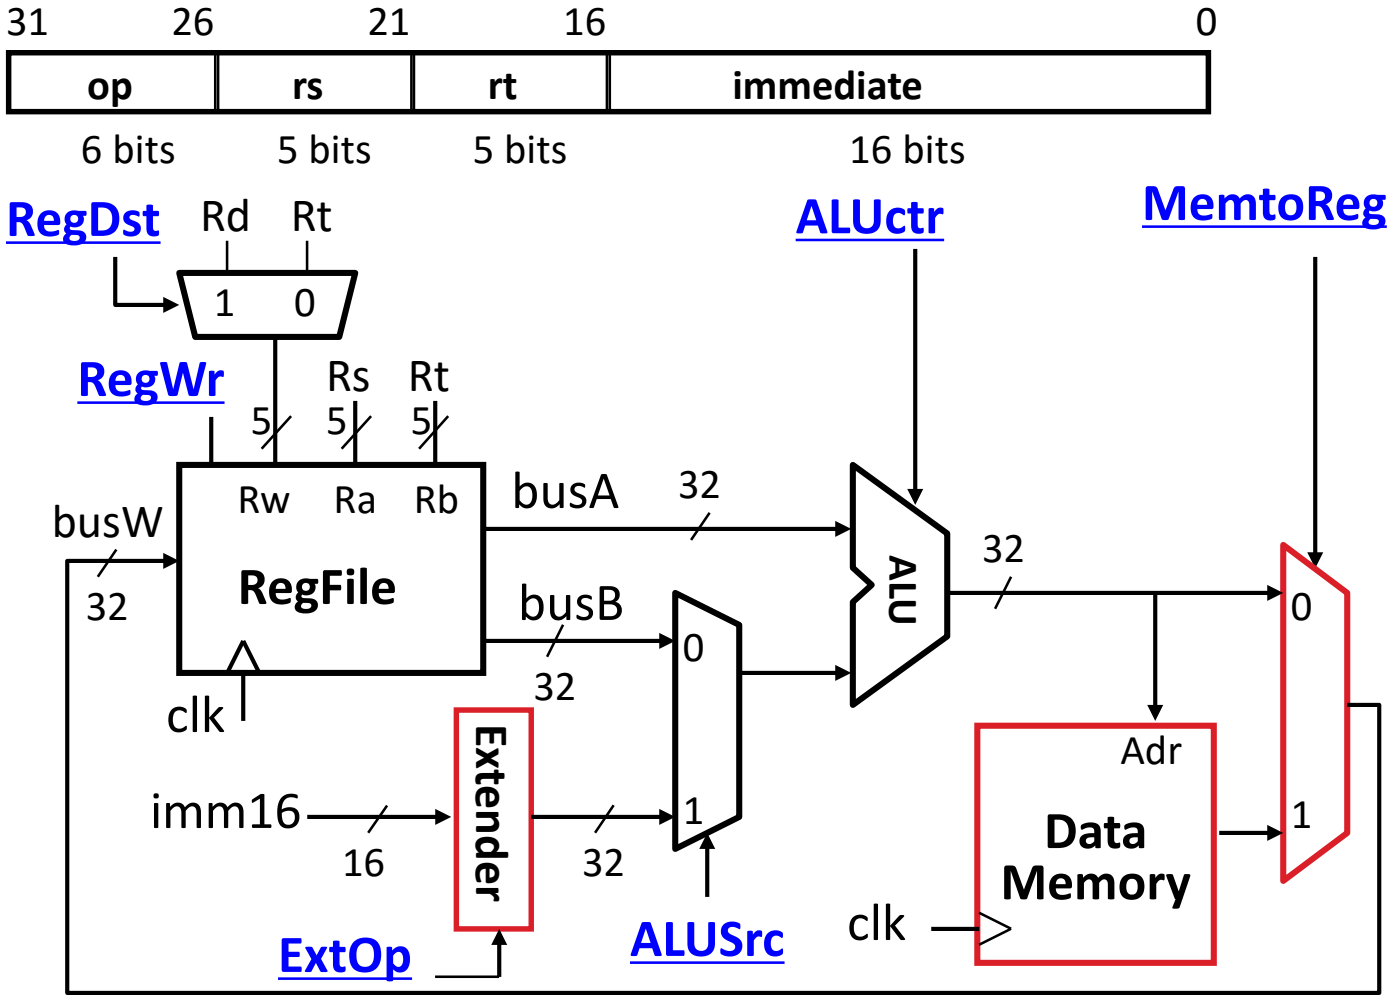


Writing to Rt register (not Rd)!!

What about Rt Read?

3d: Load Operations

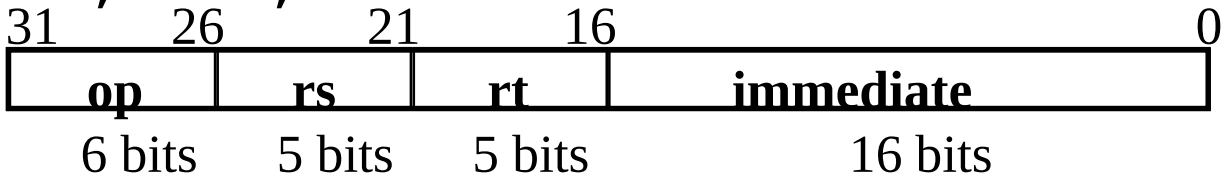
- R[rt] = Mem[R[rs] + SignExt[imm16]]
  Example: `lw rt,rs,imm16`

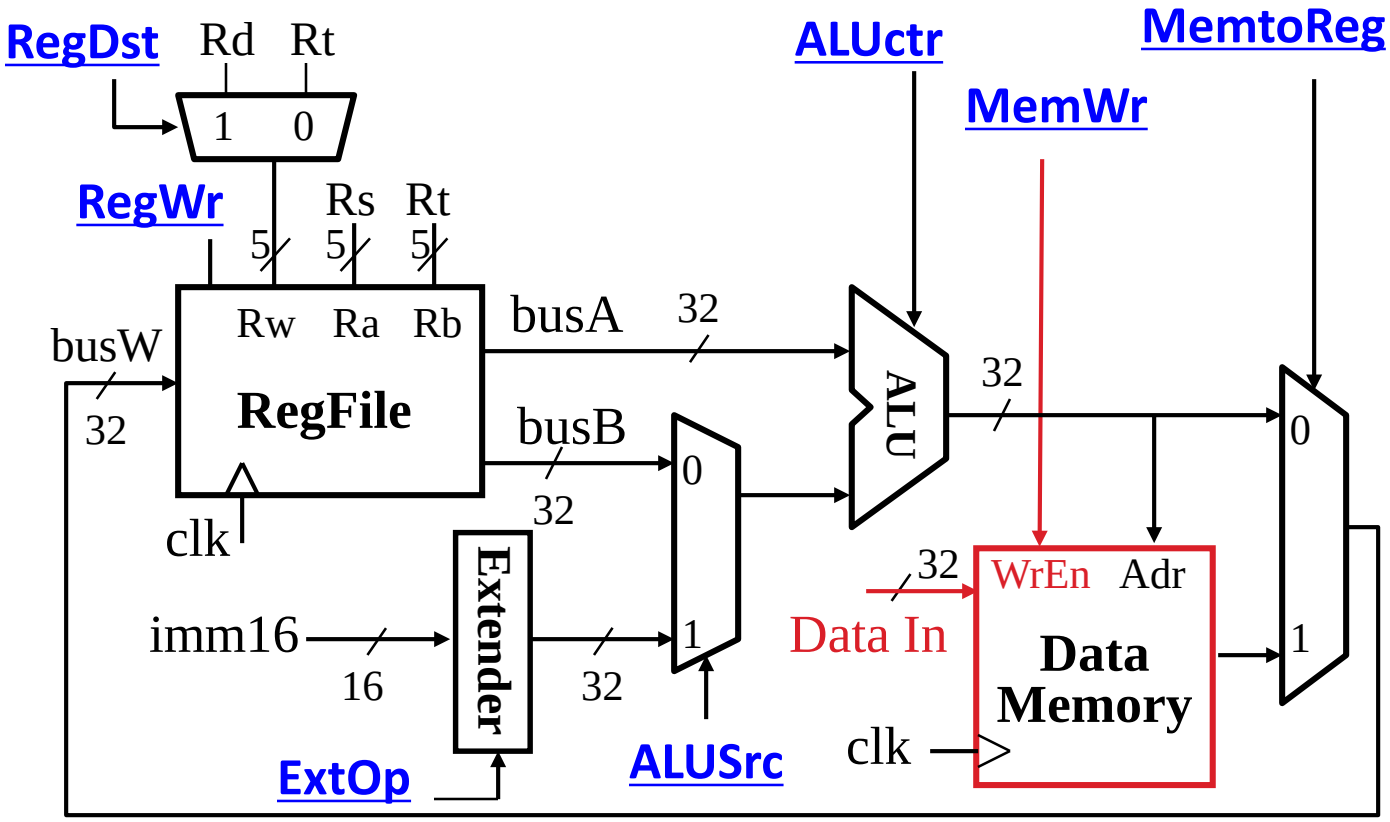


3e: Store Operations

- Mem[R[rs] + SignExt[imm16]] = R[rt]

  Ex.: `sw rt, rs, imm16`

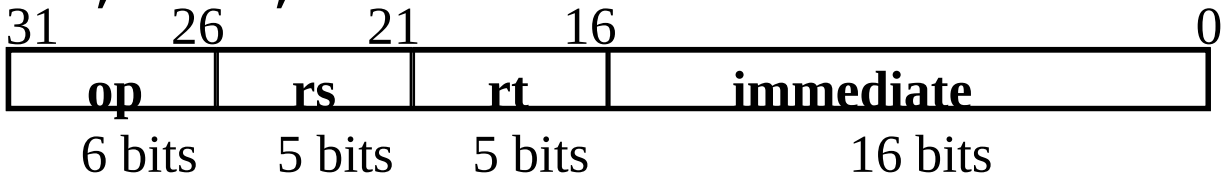


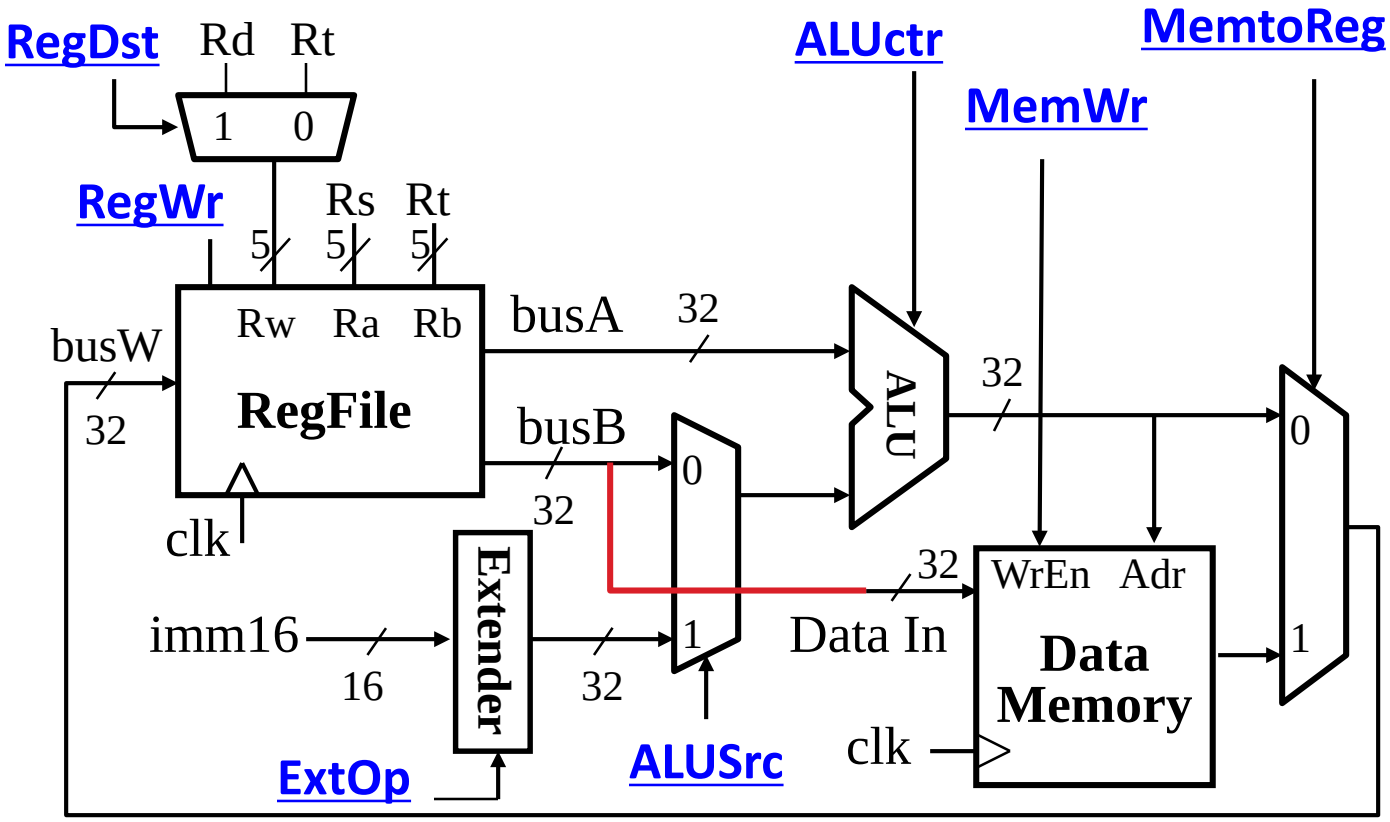


3e: Store Operations

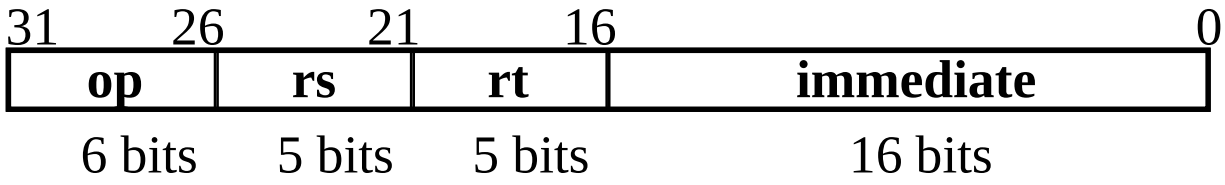
- Mem[R[rs] + SignExt[imm16]] = R[rt]

  Ex.: `sw rt, rs, imm16`





3f: The Branch Instruction



`beq rs, rt, imm16`

– mem[PC] Fetch the instruction from memory

– Equal = (R[rs] == R[rt]) Calculate branch condition

– if (Equal) Calculate the next instruction's address

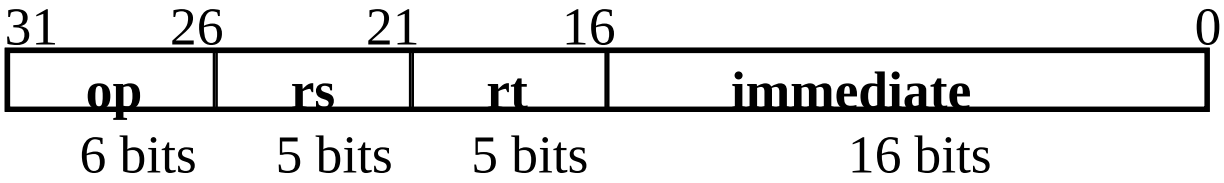
- PC = PC + 4 + (SignExt(imm16) x 4)

else

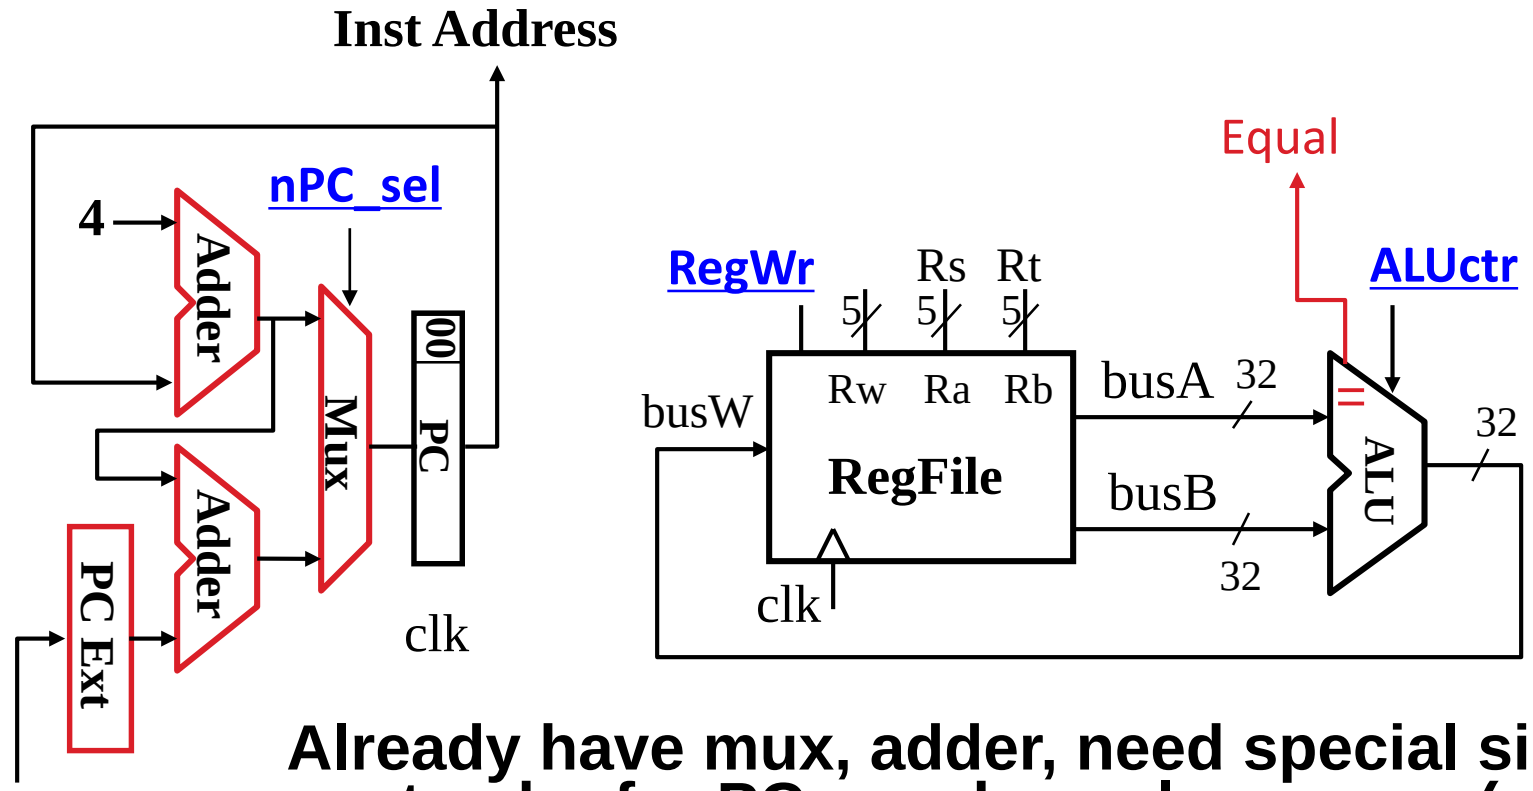
- PC = PC + 4

Datapath for Branch Operations

beq rs, rt, imm16

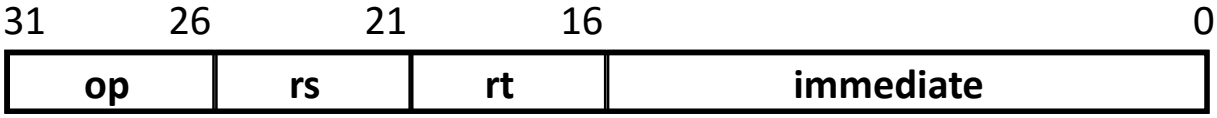


Datapath generates condition (Equal)

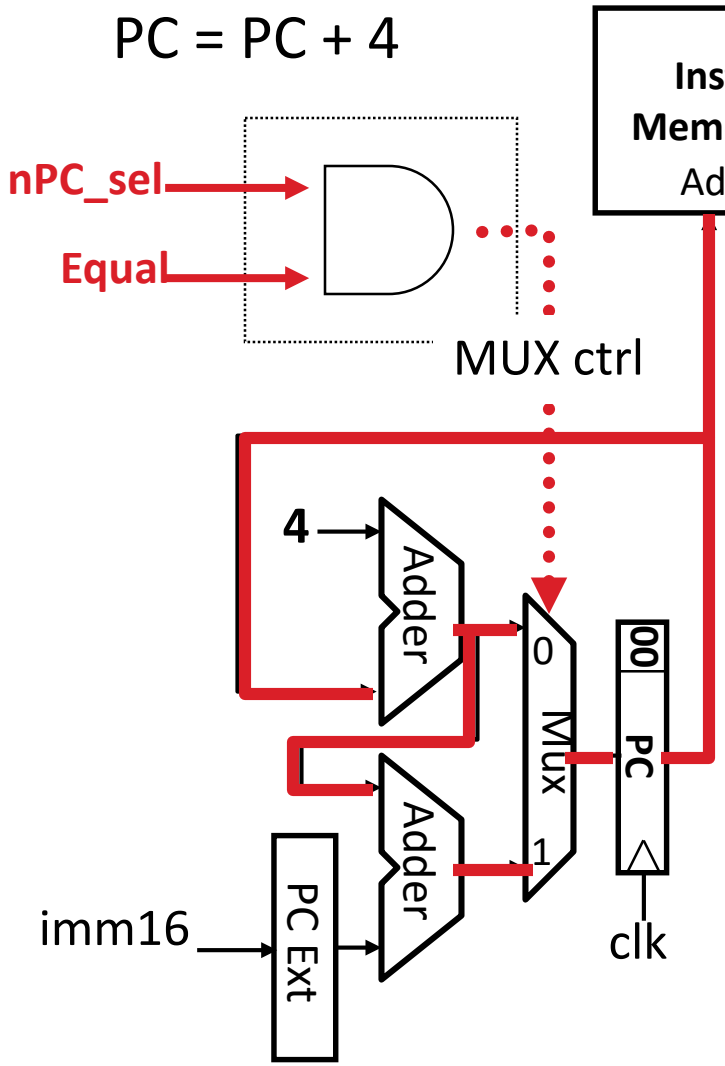


Already have mux, adder, need special sign extender for PC, need equal compare (sub?)

Instruction Fetch Unit including Branch



- if (Zero == 1) then PC = PC + 4 + SignExt[imm16]*4 ; else PC = PC + 4

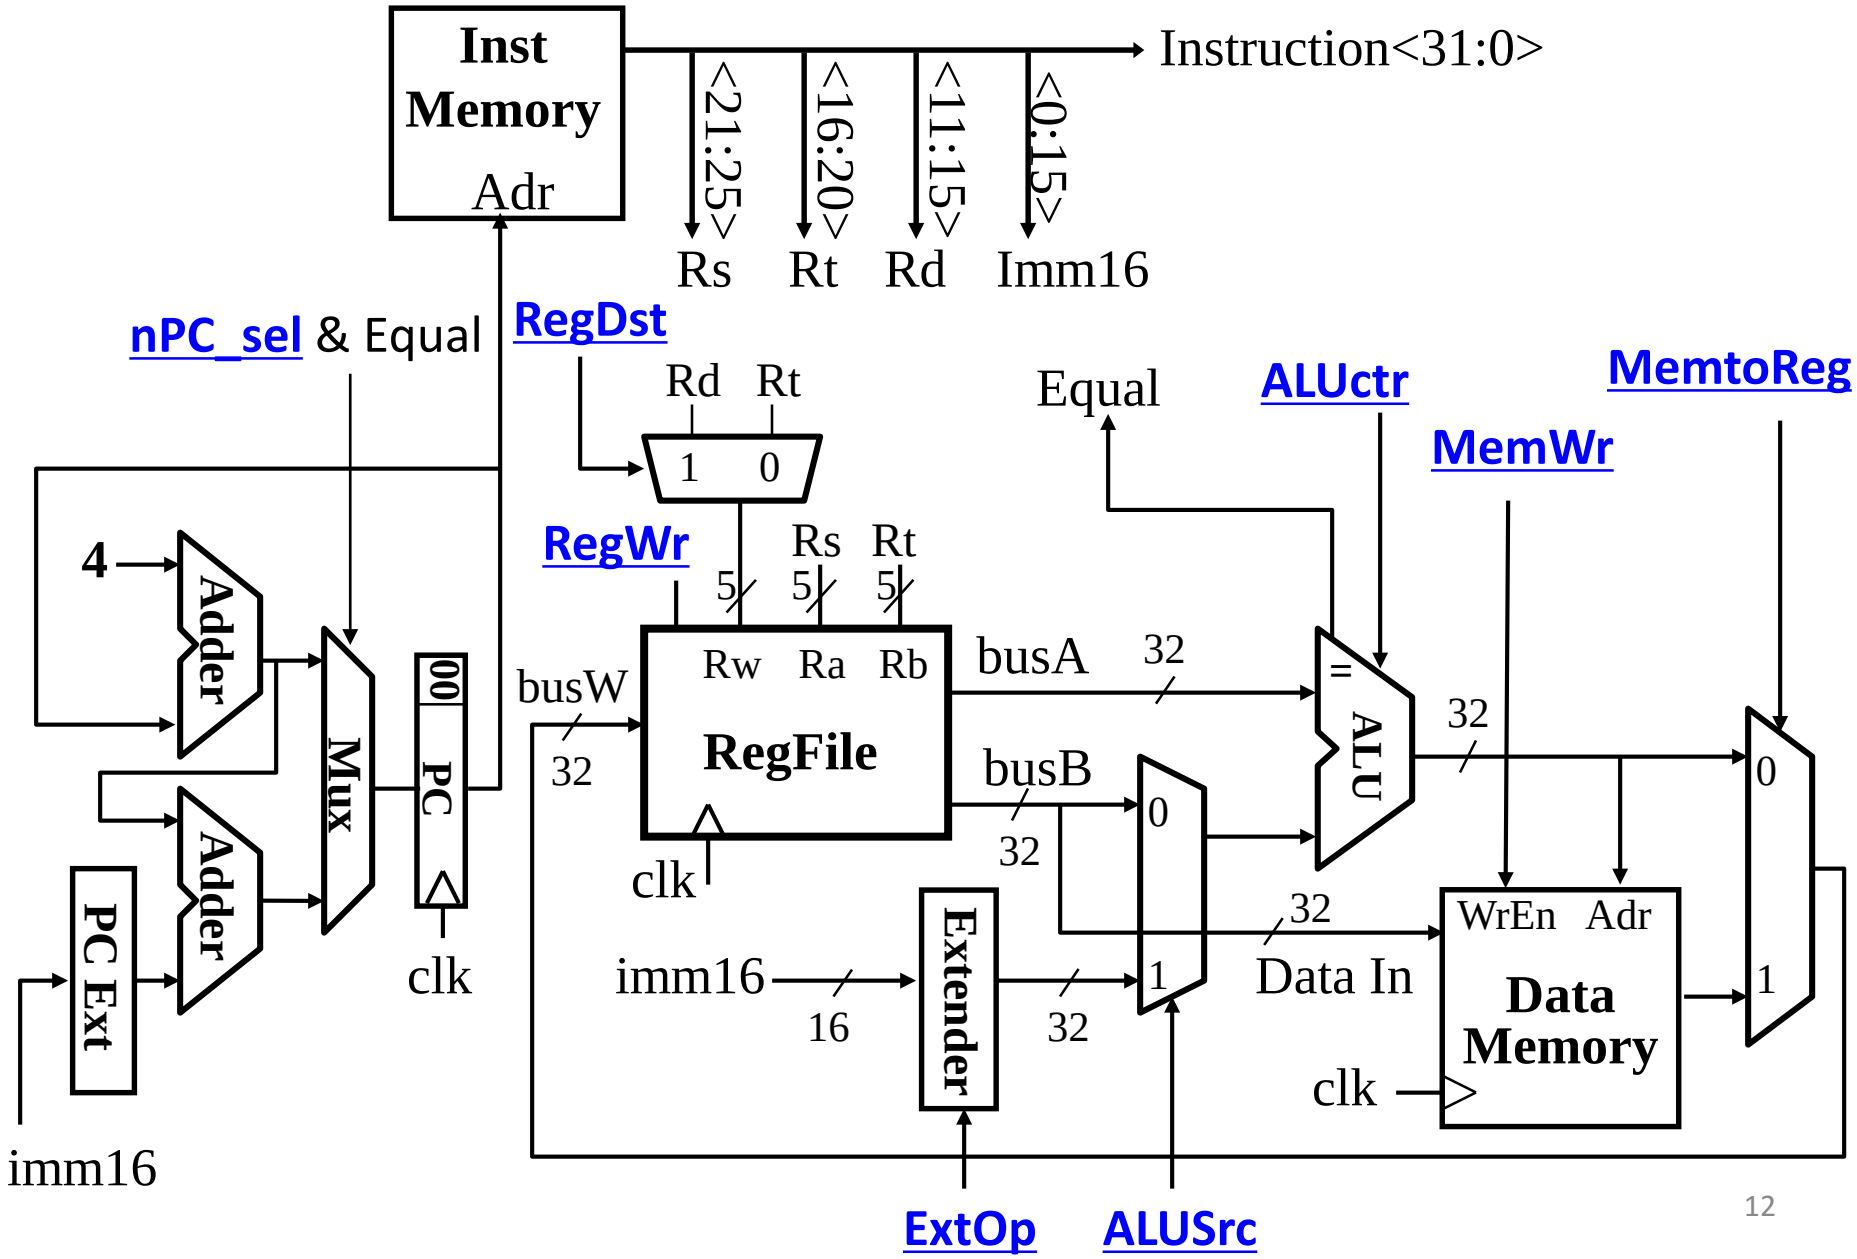


- How to encode nPC_sel?
  - Direct MUX select?
  - Branch inst. / not branch inst.
- Let's pick 2nd option

nPC_sel	zero?	MUX
0	x	0
1	0	0
1	1	1

Q: What logic gate?

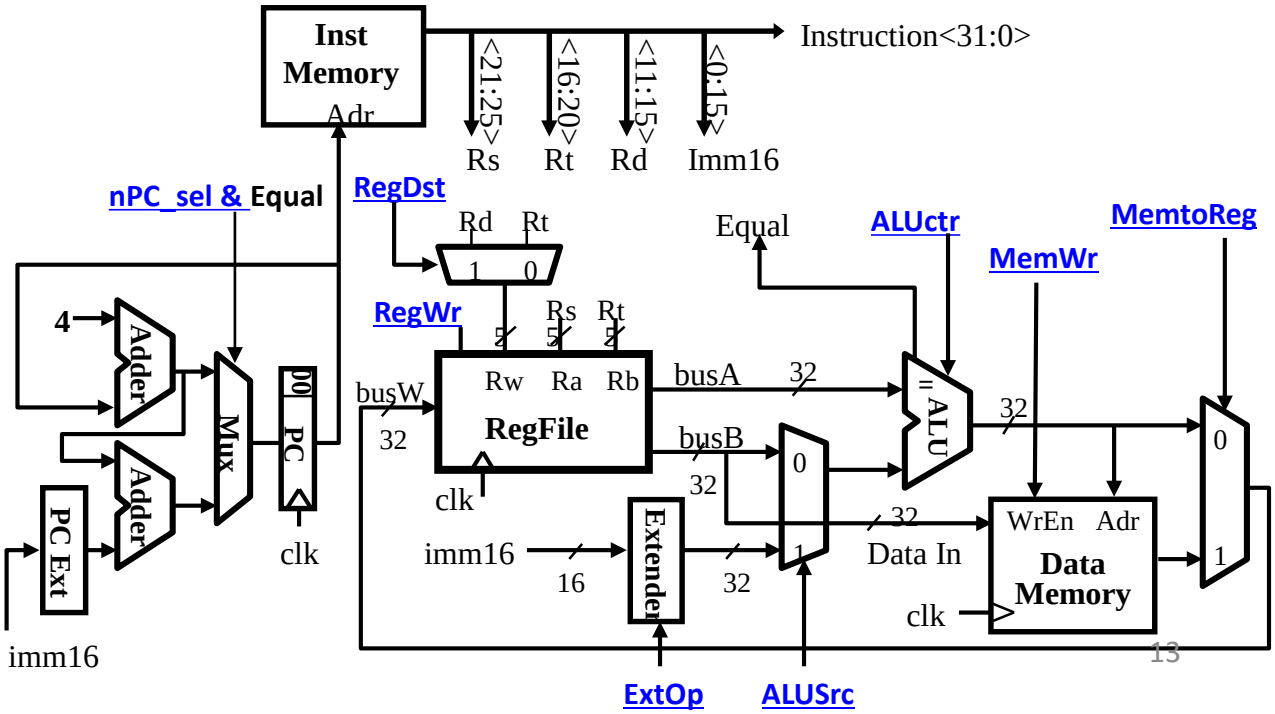
Putting it All Together:A Single Cycle Datapath



Clickers/Peer Instruction

What new instruction would need no new datapath hardware?

- A: branch if reg==immediate
- B: add two registers and branch if result zero
- C: store with auto-increment of base address:
  - sw rt, rs, offset // rs incremented by offset after store
- D: shift left logical by two bits



Administrivia

- Midterm
  - A: Super Hard
  - …
  - E: Too Easy
- Project 2-2 due 10/11
  - A: Haven't started
  - B: Done with Step 1
  - C: Done with Step 2
  - D: Done with Step 3
  - E: Finished

Processor Design: 5 steps

Step 1: Analyze instruction set to determine datapath requirements

- Meaning of each instruction is given by register transfers
- Datapath must include storage element for ISA registers
- Datapath must support each register transfer

Step 2: Select set of datapath components & establish clock methodology

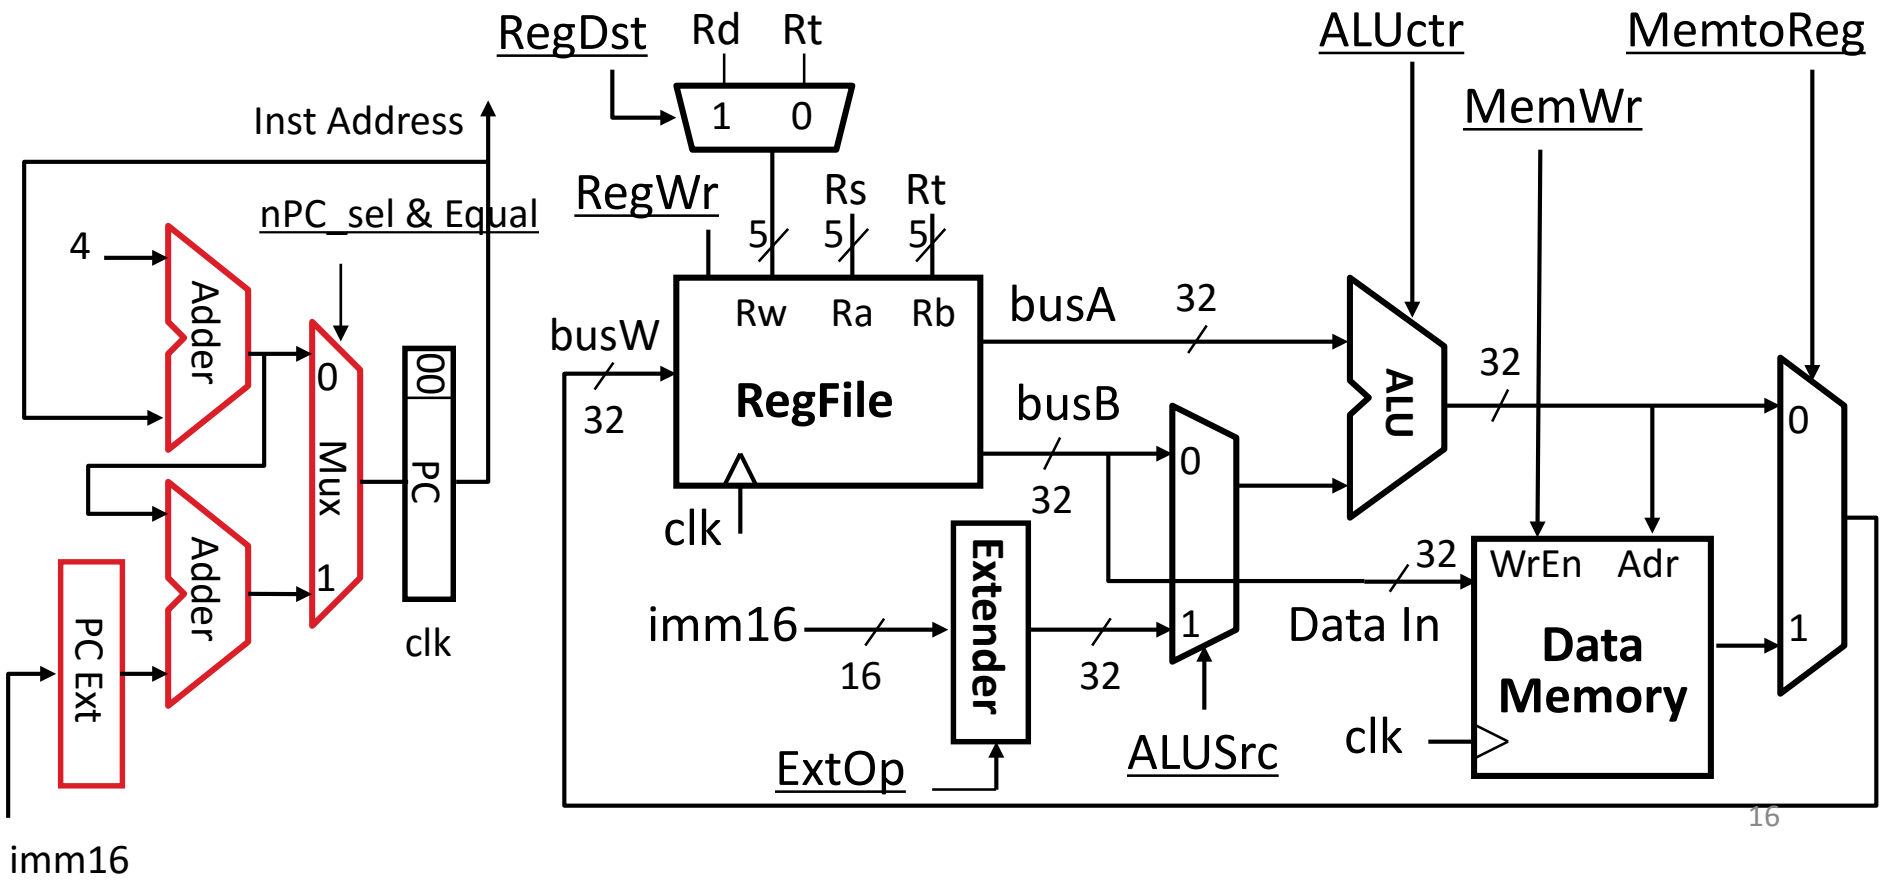
Step 3: Assemble datapath components that meet the requirements

Step 4: Analyze implementation of each instruction to determine setting of control points that realizes the register transfer

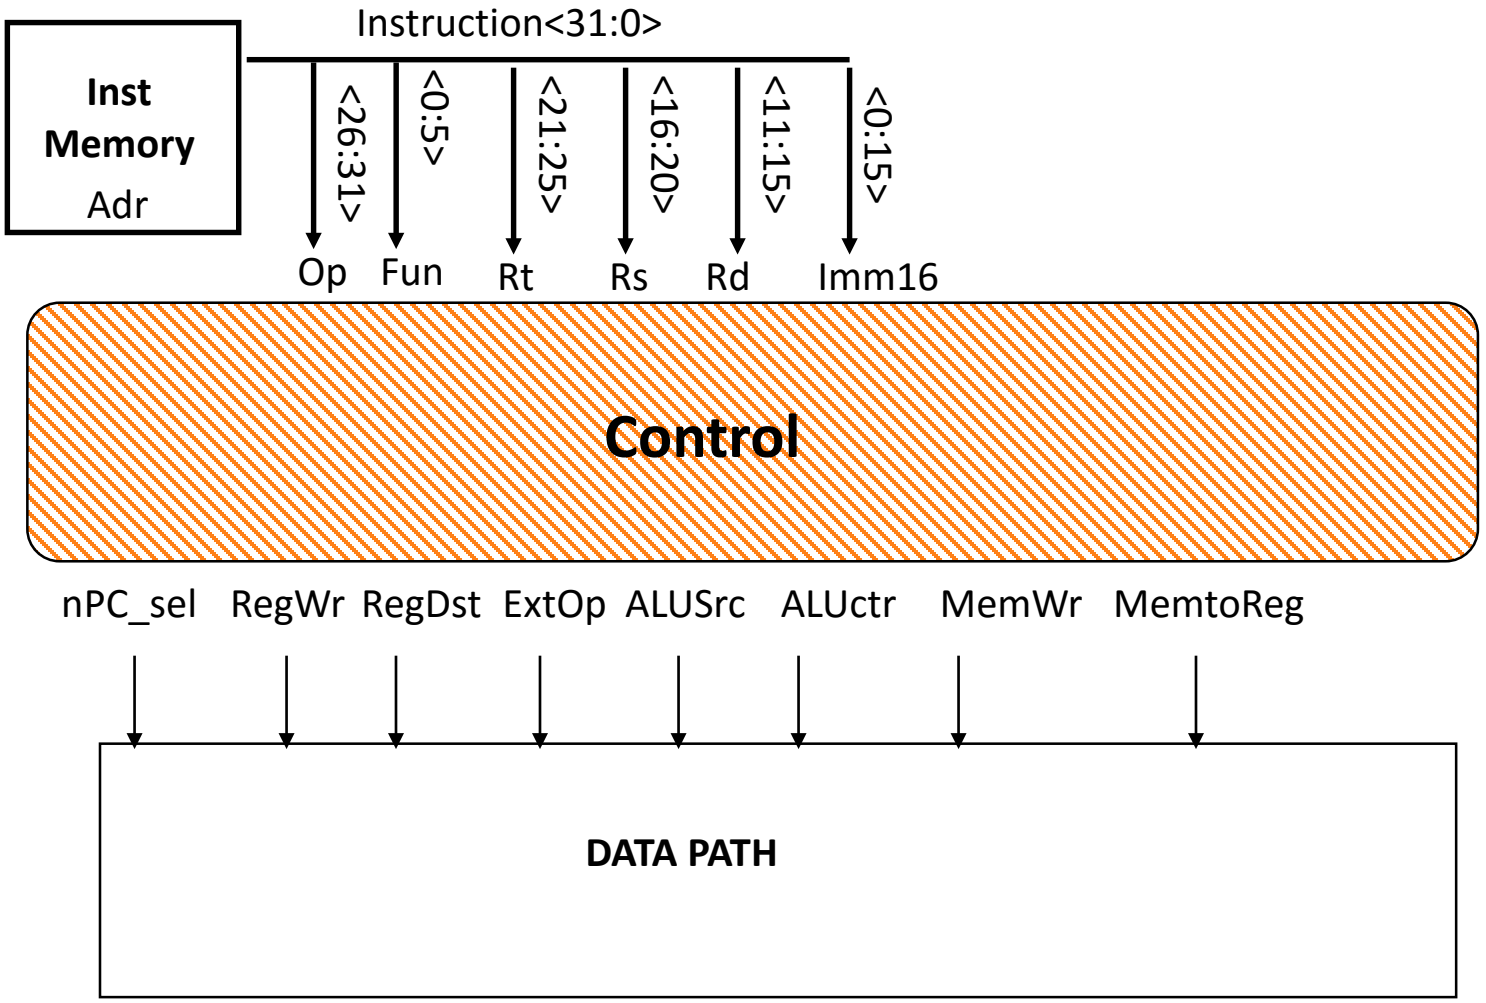
Step 5: Assemble the control logic

Datapath Control Signals

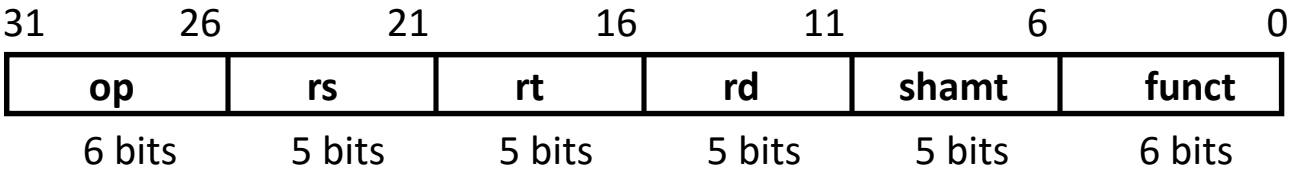
- ExtOp: "zero", "sign"
- ALUsrc: 0 ⇒ regB; 1 ⇒ immed
- ALUctr: "ADD", "SUB", "OR"
- MemWr: 1 ⇒ write memory
- MemtoReg: 0 ⇒ ALU; 1 ⇒ Mem
- RegDst: 0 ⇒ "rt"; 1 ⇒ "rd"
- RegWr: 1 ⇒ write register



Given Datapath: RTL → Control



RTL: The Add Instruction

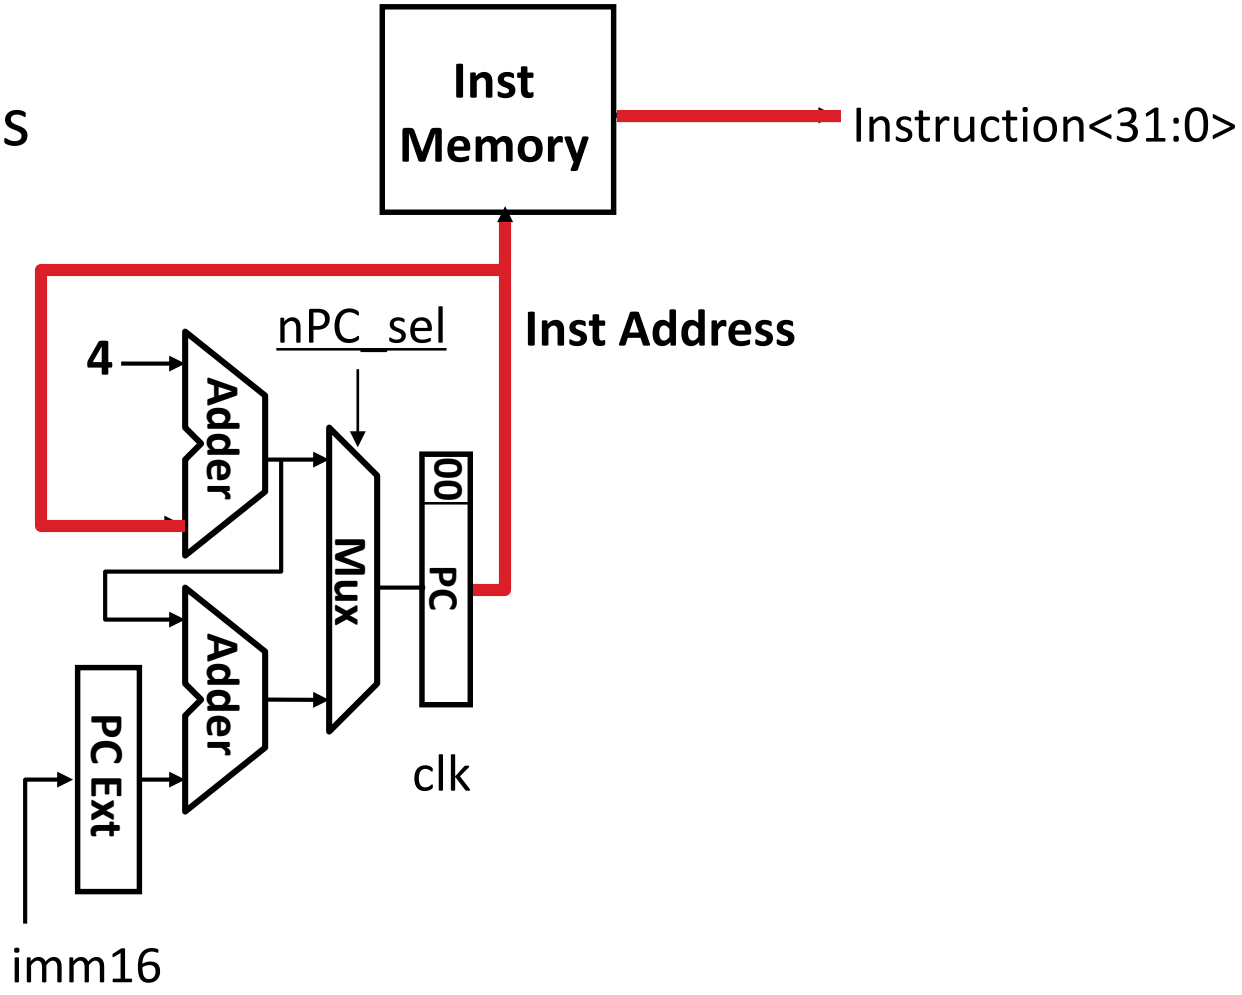


`add rd, rs, rt`

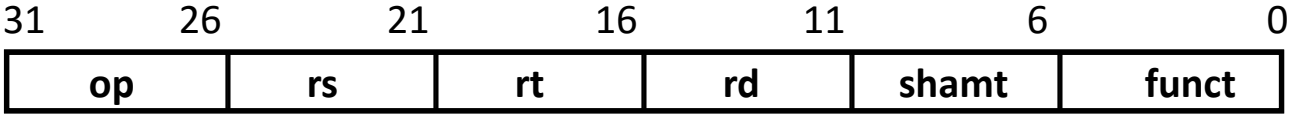
- MEM[PC] Fetch the instruction from memory
- R[rd] = R[rs] + R[rt] The actual operation
- PC = PC + 4 Calculate the next instruction's address

Instruction Fetch Unit at the Beginning of Add

- Fetch the instruction from Instruction memory: Instruction = MEM[PC]
  - same for all instructions



Single Cycle Datapath during Add



R[rd] = R[rs] + R[rt]

Instruction Fetch Unit at End of Add

- PC = PC + 4
  - Same for all instructions except: Branch and Jump

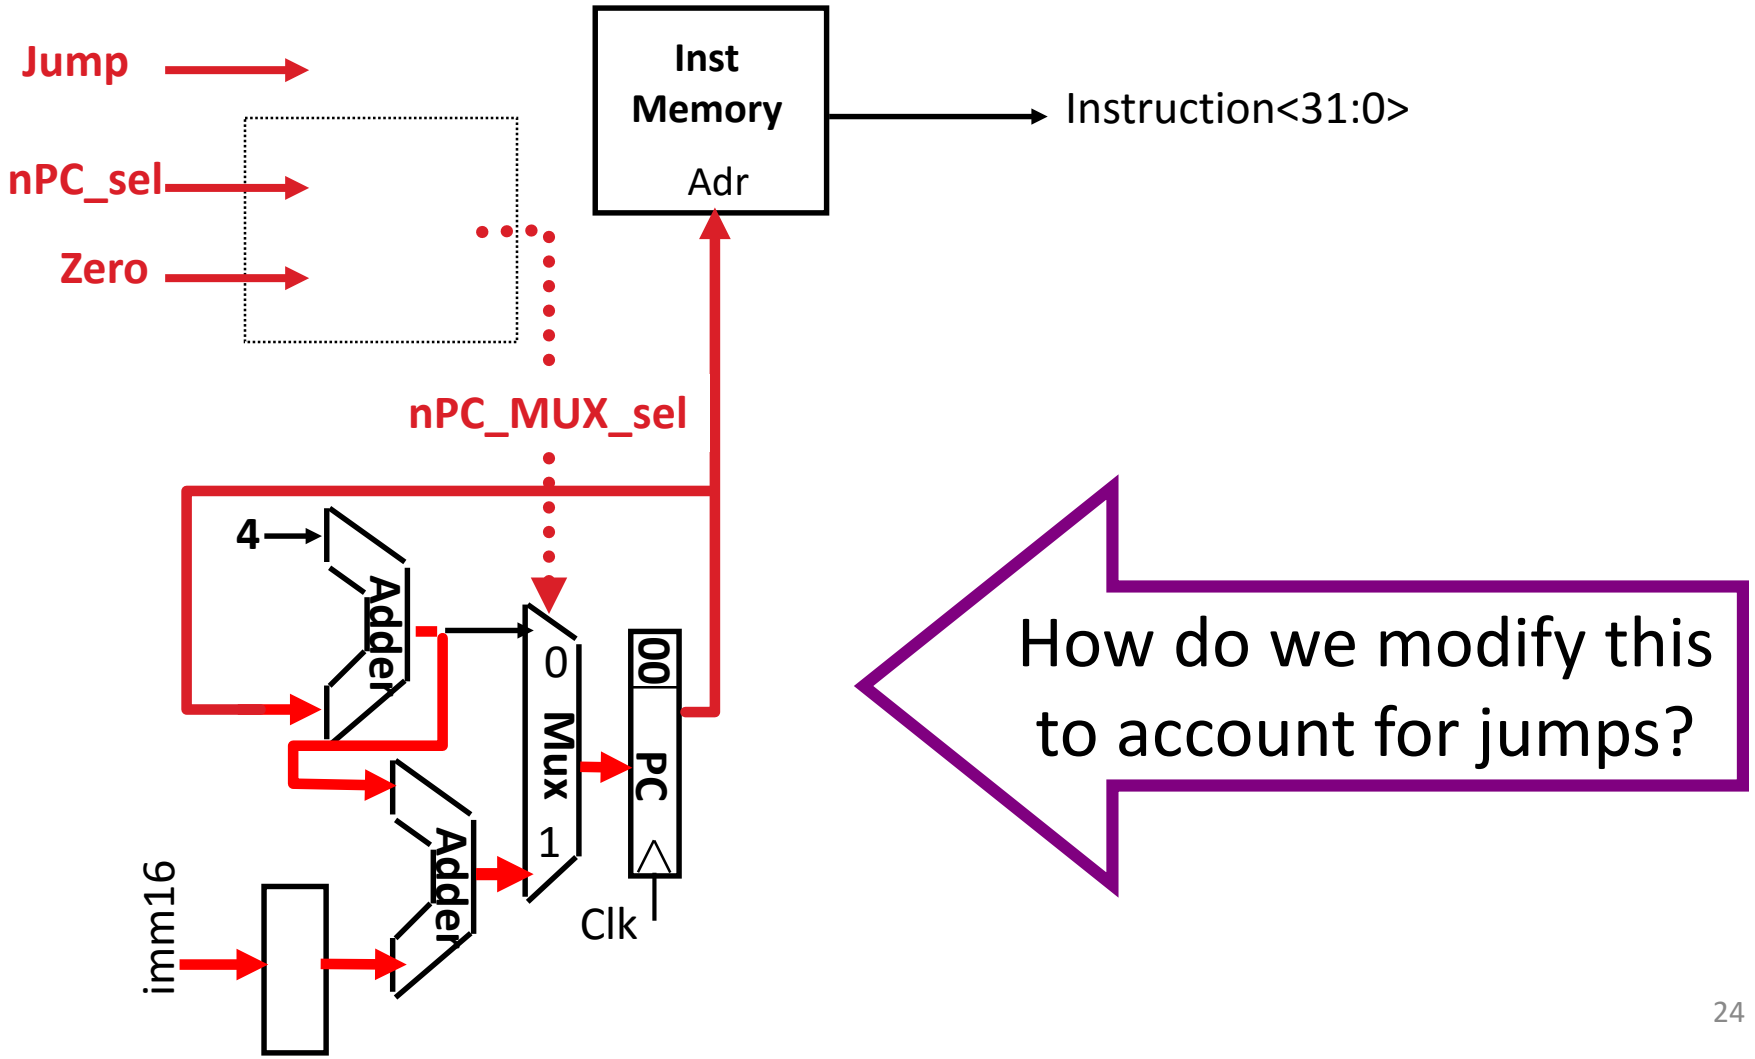
Instruction Fetch Unit at the End of Jump

- New PC = { PC[31..28], target address, 00 }



How do we modify this to account for jumps?

Instruction Fetch Unit at the End of Jump

Query

- Can Zero still get asserted?
- Does nPC_sel need to be 0?
  - If not, what?

Clicker Question

Which of the following is TRUE?

A. The clock can have a shorter period for instructions that don't use memory
B. The ALU is used to set PC to PC+4 when necessary
C. Worst-delay path in Instruction Fetch unit is Add+mux delay
D. The CPU's control needs only *opcode* to determine the next PC value to select
E. npc_sel affects the next PC address on a *jump*

Boolean Expressions for Controller

```
RegDst    = add + sub
ALUSrc    = ori + lw + sw
MemtoReg  = lw
RegWrite  = add + sub + ori + lw
MemWrite  = sw
nPCsel    = beq
Jump      = jump
ExtOp     = lw + sw
ALUctr[0] = sub + beq   (assume ALUctr is 00 ADD, 01 SUB, 10 OR)
ALUctr[1] = or
```

Where:

$$rtype = \sim op_5 \bullet \sim op_4 \bullet \sim op_3 \bullet \sim op_2 \bullet \sim op_1 \bullet \sim op_0,$$
$$ori = \sim op_5 \bullet \sim op_4 \bullet op_3 \bullet op_2 \bullet \sim op_1 \bullet op_0$$
$$lw = op_5 \bullet \sim op_4 \bullet \sim op_3 \bullet \sim op_2 \bullet op_1 \bullet op_0$$

Summary: Single-cycle Processor

- Five steps to design a processor:
  1. Analyze instruction set → datapath requirements
  2. Select set of datapath components & establish clock methodology
  3. Assemble datapath meeting the requirements
  4. Analyze implementation of each instruction to determine setting of control points that effects the register transfer.
  5. Assemble the control logic
     - Formulate Logic Equations
     - Design Circuits
