

## Virtual Memory Overview

**Virtual address (VA):** What your program uses

|                     |             |
|---------------------|-------------|
| Virtual Page Number | Page Offset |
|---------------------|-------------|

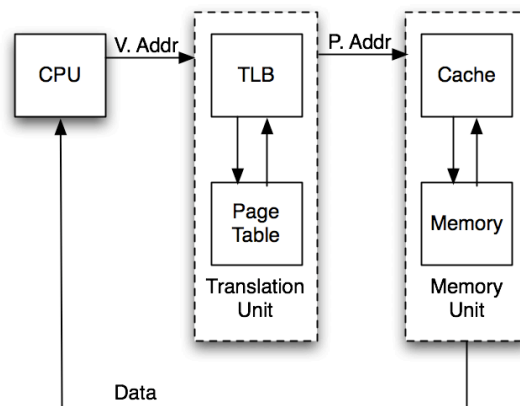

**Physical address (PA):** What actually determines where in memory to go

|                      |             |
|----------------------|-------------|
| Physical Page Number | Page Offset |
|----------------------|-------------|

With 4 KiB pages and byte addresses,  $2^{(page\ offset\ bits)} = 4096$ , so page offset bits = 12.

### The Big Picture: Logical Flow

Translate VA to PA using the TLB and Page Table. Then use PA to access memory as the program intended.

### Pages

A chunk of memory or disk with a set size. Addresses in the same virtual page get mapped to addresses in the same physical page. The page table determines the mapping.

### The Page Table

| Index = Virtual Page Number<br>(not stored) | Page Valid | Page Dirty | Permission Bits<br>(read, write, ...) | Physical Page Number |
|---|------------|------------|---------------------------------------|----------------------|
| 0   |            |            |                                       |                      |
| 1   |            |            |                                       |                      |
| 2   |            |            |                                       |                      |
| ...   |            |            |                                       |                      |
| (Max virtual page number)                   |            |            |                                       |                      |

Each stored row of the page table is called a **page table entry** (the grayed section is the first page table entry). The page table is stored *in memory*; the OS sets a register telling the hardware the address of the first entry of the page table. The processor updates the “page dirty” in the page table: “page dirty” bits are used by the OS to know whether updating a page on disk is necessary. Each process gets its own page table.

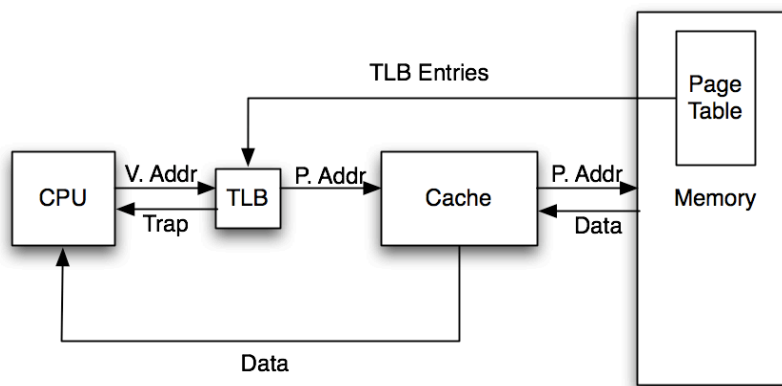

- **Protection Fault**--The page table entry for a virtual page has permission bits that prohibit the requested operation
- **Page Fault**--The page table entry for a virtual page has its valid bit set to false. The entry is not in memory.

### The Translation Lookaside Buffer (TLB)

A cache for the page table. Each block is a single page table entry. If an entry is not in the TLB, it's a TLB miss. Assuming *fully associative*:

|                 |                           |                  |                 |                      |
|-----------------|---------------------------|------------------|-----------------|----------------------|
| TLB Entry Valid | Tag = Virtual Page Number | Page Table Entry |                 |                      |
|                 |                           | Page Dirty       | Permission Bits | Physical Page Number |
| ...             | ...                       | ...              | ...             | ...                  |

### The Big Picture Revisited

### Exercises

- 1) What are three specific benefits of using virtual memory?
- 2) What should happen to the TLB when a new value is loaded into the page table address register?
- 3) x86 has an "accessed" bit in each page table entry, which is like the dirty bit but set whenever a page is used (load *or* store). Why is this helpful when using memory as a cache for disk?

4) Fill this table out!

| Virtual Address Bits | Physical Address Bits | Page Size | VPN Bits | PPN Bits | Bits per row of PT (4 extra bits) |
|----------------------|-----------------------|-----------|----------|----------|-----------------------------------|
| 32                   | 32                    | 16KB      |          |          |                                   |
| 32                   | 26                    |           |          | 13       |                                   |
|                      | 32                    |           | 21       |          | 21                                |
|                      |                       | 32KB      | 25       |          | 25                                |
| 64                   |                       |           | 48       |          | 28                                |
