

# CS61c Summer 2014 Discussion 4 – MIPS Procedures

## 1 MIPS Control Flow

There are only two instructions necessary for creating and calling functions: `jal` and `jr`. If you follow register conventions when calling functions, you will be able to write much simpler and cleaner MIPS code.

## 2 Conventions

1. How should `$sp` be used? When do we add or subtract from `$sp`?
2. Which registers need to be saved or restored before using `jr` to return from a function?
3. Which registers need to be saved before using `jal`?
4. How do we pass arguments into functions?
5. What do we do if there are more than four arguments to a function?
6. How are values returned by functions?

When calling a function in MIPS, who needs to save the following registers to the stack? Answer "caller" for the procedure making a function call, "callee" for the function being called, or "N.A" for neither.

<code>\$0</code>	<code>\$v*</code>	<code>\$a*</code>	<code>\$t*</code>	<code>\$s*</code>	<code>\$sp</code>	<code>\$ra</code>

Now assume a function `foo` calls another function `bar`, which is known to call some other functions. `foo` takes one argument and will modify and use `$t0` and `$s0`. `bar` takes two arguments, returns an integer, and uses `$t0-$t2` and `$s0-$s1`. In the boxes below, draw a possible ordering of the stack just before `bar` calls a function. The top left box is the address of `$sp` when `foo` is first called, and the stack goes downwards, continuing at each next column. Add "(f)" if the register is stored by `foo` and "(b)" if the register is stored by `bar`. The first one is written in for you.

1 <code>\$ra</code> (f)	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

### 3 A Guide to Writing Functions

```
FunctionFoo: # PROLOGUE
             # begin by reserving space on the stack

             # now, store needed registers

             # BODY
             ...
             # EPILOGUE
             # restore registers

             # release stack spaces

             # return to normal execution
```

### 4 C to MIPS

1. Assuming \$a0 and \$a1 hold integer pointers, swap the values they point via the stack and return control.

```
void swap(int *a, int *b) {

    int tmp = *a;
    *a = *b;
    *b = tmp;

}
```

2. Translate the following algorithm that finds the  $N^{th}$  Fibonacci number to MIPS assembly. Assume \$s0 holds N, \$s1 holds fib, \$t0 holds i, and \$t1 hold j.

```
int fib = 1, i = 1, j = 1;

if (N==0)      return 0;
else if (N==1) return 1;
N -= 2;

while (N != 0) {
    fib = i + j;
    j = i;
    i = fib;
    N--;
}

return fib;
```

What must be done to make this algorithm a callable MIPS function?
