

### 1. True or False

For each of the following claims, state whether the claim is true or false. If it is true, give a *short* proof; if it is false, give a *simple* counterexample.

- (a) In a stable marriage instance, if man  $m$  and woman  $w$  each put each other at the top of their respective preference lists, then  $m$  must be paired with  $w$  in every stable matching.
  
  
  
  
  
  
  
  
  
  
- (b) In a stable marriage instance with at least two men and two women, if man  $m$  and woman  $w$  each put each other at the bottom of their respective preference lists, then  $m$  cannot be paired with  $w$  in any stable pairing.

### 2. Propose-and-Reject Proofs

Prove the following statements about the traditional propose-and-reject algorithm.

- (a) In any execution of the algorithm, if a woman receives a proposal on day  $i$ , then she receives some proposal on every day thereafter until termination.
  
  
  
  
  
  
  
  
  
  
- (b) In any execution of the algorithm that takes  $k$  days, there must be some woman who does not receive a proposal in day  $k - 1$ .
  
  
  
  
  
  
  
  
  
  
- (c) In any execution of the algorithm, if a woman receives no proposal on day  $i$ , then she receives no proposal on any previous day  $j$ ,  $1 \leq j < i$ .

- (d) In any execution of the algorithm, there is at least one woman who only receives a single proposal (Hint: use the parts above!)

### 3. Good, Better, Best

In a particular instance of the stable marriage problem with  $n$  men and  $n$  women, it turns out that there are exactly three distinct stable matchings,  $M_1$ ,  $M_2$ , and  $M_3$ . Also, each man  $m$  has a different partner in the three matchings. Therefore each man has a clear preference ordering of the three matchings (according to the ranking of his partners in his preference list). Now, suppose for man  $m_1$ , this order is  $M_1 > M_2 > M_3$ .

Prove that every man has the same preference ordering  $M_1 > M_2 > M_3$ .

### 4. Pairing Up

Prove that for every even  $n \geq 2$ , there exists an instance of the stable marriage problem with  $n$  men and  $n$  women such that the instance has at least  $2^{n/2}$  distinct stable matchings.
