

Inverses

Today: finding inverses quickly.

Euclid's Algorithm.

Runtime.

Euclid's Extended Algorithm.

Announcements

From Allen!

1. Starting hw3 checkoff, student will only have two tries at most. The higher grade will be final.

Study for the first one!!!

2. OHs and Homework party on Monday and Tuesday, possibly Wednesday are busy with HW checkoff. But usually the early morning (before 12) ones are not crowded, sometimes even empty. Also, Thursday and Friday's are also good choices to avoid the crowds.

3. In order to balance the situation mentioned above, the tutoring deadline is extended to Thursday. Every week but for Thanksgiving. (Something special that week.)

Refresh

Does 2 have an inverse mod 8? No.

Any multiple of 2 is 2 away from $0 + 8k$.

Does 2 have an inverse mod 9? Yes. 5

$$2(5) = 10 = 1 \pmod{9}.$$

Does 6 have an inverse mod 9? No.

Any multiple of 6 is 3 away from $0 + 9k$.

x has an inverse modulo m if and only if

$\gcd(x, m) > 1$? No.

$\gcd(x, m) = 1$? Yes.

Today:

Compute gcd!

Compute Inverse modulo m .

Divisibility...

Notation: $d|x$ means “ d divides x ” or
 $x = kd$ for some integer k .

Fact: If $d|x$ and $d|y$ then $d|(x + y)$ and $d|(x - y)$.

Proof: $d|x$ and $d|y$ or

$$x = \ell d \text{ and } y = kd$$

$$\implies x - y = kd - \ell d = (k - \ell)d \implies d|(x - y)$$

More divisibility

Notation: $d|x$ means “ d divides x ” or
 $x = kd$ for some integer k .

Lemma 1: If $d|x$ and $d|y$ then $d|y$ and $d| \text{ mod}(x, y)$.

Proof:

$$\begin{aligned}\text{mod}(x, y) &= x - \lfloor x/y \rfloor \cdot y \\ &= x - \lfloor s \rfloor \cdot y \quad \text{for integer } s \\ &= kd - s\ell d \quad \text{for integers } k, \ell \\ &= (k - s\ell)d\end{aligned}$$

Therefore $d| \text{ mod}(x, y)$. And $d|y$ since it is in condition. □

Lemma 2: If $d|y$ and $d| \text{ mod}(x, y)$ then $d|y$ and $d|x$.

Proof...: Similar. Try this at home. □ish.

GCD Mod Corollary: $\text{gcd}(x, y) = \text{gcd}(y, \text{ mod}(x, y))$.

Proof: x and y have **same** set of common divisors as x and $\text{mod}(x, y)$ by Lemma.

Same common divisors \implies largest is the same. □

Euclid's algorithm.

GCD Mod Corollary: $\gcd(x, y) = \gcd(y, \text{mod}(x, y))$.

```
(define (gcd x y)
  (if (= y 0)
      x
      (gcd y (mod x y)))) ***
```

Theorem: Euclid's algorithm computes the greatest common divisor of x and y if $x \geq y$.

Proof: Use Strong Induction.

Base Case: $y = 0$, “ x divides y and x ”

\implies “ x is common divisor and clearly largest.”

Induction Step: $\text{mod}(x, y) < y \leq x$ when $x \geq y$

call in **line (***)** meets conditions plus arguments “smaller”

and by strong induction hypothesis

computes $\gcd(x, \text{mod}(x, y))$

which is $\gcd(x, y)$ by GCD Mod Corollary. □

Excursion: Value and Size.

Before discussing running time of gcd procedure...

What is the value of 1,000,000?

one million or 1,000,000!

What is the “size” of 1,000,000?

Number of digits: 7.

Number of bits: 21.

For a number x , what is its size in bits?

$$n = b(x) \approx \log_2 x$$

GCD procedure is fast.

Theorem: GCD uses $2n$ "divisions" where n is the number of bits.

Is this good? Better than trying all numbers in $\{2, \dots, y/2\}$?

Check 2, check 3, check 4, check 5 . . . , check $y/2$.

2^{n-1} divisions! Exponential dependence on size!

101 bit number. $2^{100} \approx 10^{30} =$ "million, trillion, trillion" divisions!

$2n$ is much faster! .. roughly 200 divisions.

Algorithms at work.

Trying everything

Check 2, check 3, check 4, check 5 . . . , check $y/2$.

“(gcd x y)” at work.

```
gcd(700, 568)
  gcd(568, 132)
    gcd(132, 40)
      gcd(40, 12)
        gcd(12, 4)
          gcd(4, 0)
            4
```

Notice: The first argument decreases rapidly.

At least a factor of 2 in two recursive calls.

(The second is less than the first.)

Proof.

```
(define (gcd x y)
  (if (= y 0)
      x
      (gcd y (mod x y))))
```

Theorem: GCD uses $O(n)$ "divisions" where n is the number of bits.

Proof:

Fact:

First arg decreases by at least factor of two in two recursive calls.

Proof of Fact: Recall that first argument decreases every call. After $2 \log_2 x = O(n)$ recursive calls, argument x is 1 or number.

One more recursive call to finish: "mod(x,y) \leq x/2."

Case 1: $y \leq x/2$, first argument is y .

Division per recursive call: $\text{mod}(x,y)$ is second argument in next recursive call, $O(n)$ divisions, and becomes the first argument in the next one. □

$$\text{mod}(x,y) = x - y \lfloor \frac{x}{y} \rfloor = x - y \leq x - x/2 = x/2$$

□

Finding an inverse?

We showed how to efficiently tell if there is an inverse.

Extend euclid to find inverse.

Euclid's GCD algorithm.

```
(define (gcd x y)
  (if (= y 0)
      x
      (gcd y (mod x y))))
```

Computes the $\text{gcd}(x, y)$ in $O(n)$ divisions.

For x and m , if $\text{gcd}(x, m) = 1$ then x has an inverse modulo m .

Multiplicative Inverse.

GCD algorithm used to tell **if** there is a multiplicative inverse.

How do we **find** a multiplicative inverse?

Extended GCD

Euclid's Extended GCD Theorem: For any x, y there are integers a, b such that

$$ax + by = \gcd(x, y) = d \quad \text{where } d = \gcd(x, y).$$

“Make d out of sum of multiples of x and y .”

What is multiplicative inverse of x modulo m ?

By extended GCD theorem, when $\gcd(x, m) = 1$.

$$\begin{aligned} ax + bm &= 1 \\ ax &\equiv 1 - bm \equiv 1 \pmod{m}. \end{aligned}$$

So a multiplicative inverse of x if $\gcd(a, x) = 1$!!

Example: For $x = 12$ and $y = 35$, $\gcd(12, 35) = 1$.

$$(3)12 + (-1)35 = 1.$$

$$a = 3 \text{ and } b = -1.$$

The multiplicative inverse of 12 (mod 35) is 3.

Make d out of x and y ..?

```
gcd(35, 12)
  gcd(12, 11) ;; gcd(12, 35%12)
    gcd(11, 1) ;; gcd(11, 12%11)
      gcd(1, 0)
        1
```

How did gcd get 11 from 35 and 12?

$$35 - \lfloor \frac{35}{12} \rfloor 12 = 35 - (2)12 = 11$$

How does gcd get 1 from 12 and 11?

$$12 - \lfloor \frac{12}{11} \rfloor 11 = 12 - (1)11 = 1$$

Algorithm finally returns 1.

But we want 1 from sum of multiples of 35 and 12?

Get 1 from 12 and 11.

$$1 = 12 - (1)11 = 12 - (1)(35 - (2)12) = (3)12 + (-1)35$$

Get 11 from 35 and 12 and plugin.... Simplify. $a = 3$ and $b = -1$.

Extended GCD Algorithm.

```
ext-gcd(x, y)
  if y = 0 then return(x, 1, 0)
  else
    (d, a, b) := ext-gcd(y, mod(x, y))
    return (d, b, a - floor(x/y) * b)
```

Claim: Returns (d, a, b) : $d = \gcd(a, b)$ and $d = ax + by$.

Example: $a - \lfloor x/y \rfloor \cdot b = 1$

```
ext-gcd(35, 12)
  ext-gcd(12, 11)
    ext-gcd(11, 1)
      ext-gcd(1, 0)
        return (1, 1, 0) ;; 1 = (1)1 + (0) 0
      return (1, 0, 1)  ;; 1 = (0)11 + (1)1
    return (1, 1, -1)  ;; 1 = (1)12 + (-1)11
  return (1, -1, 3)   ;; 1 = (-1)35 + (3)12
```

Extended GCD Algorithm.

```
ext-gcd(x, y)
  if y = 0 then return(x, 1, 0)
  else
    (d, a, b) := ext-gcd(y, mod(x, y))
    return (d, b, a - floor(x/y) * b)
```

Theorem: Returns (d, a, b) , where $d = \gcd(a, b)$ and

$$d = ax + by.$$

Correctness.

Proof: Strong Induction.¹

Base: $\text{ext-gcd}(x, 0)$ returns $(d = x, 1, 0)$ with $x = (1)x + (0)y$.

Induction Step: Returns (d, A, B) with $d = Ax + By$

Ind hyp: $\text{ext-gcd}(y, \text{ mod}(x, y))$ returns (d, a, b) with

$$d = ay + b(\text{ mod}(x, y))$$

$\text{ext-gcd}(x, y)$ calls $\text{ext-gcd}(y, \text{ mod}(x, y))$ so

$$\begin{aligned}d &= ay + b \cdot (\text{ mod}(x, y)) \\ &= ay + b \cdot (x - \lfloor \frac{x}{y} \rfloor y) \\ &= bx + (a - \lfloor \frac{x}{y} \rfloor \cdot b)y\end{aligned}$$

And ext-gcd returns $(d, b, (a - \lfloor \frac{x}{y} \rfloor \cdot b))$ so theorem holds! □

¹Assume d is $\text{gcd}(x, y)$ by previous proof.

Review Proof: step.

```
ext-gcd(x, y)
  if y = 0 then return(x, 1, 0)
  else
    (d, a, b) := ext-gcd(y, mod(x, y))
    return (d, b, a - floor(x/y) * b)
```

Recursively: $d = ay + b(x - \lfloor \frac{x}{y} \rfloor \cdot y) \implies d = bx - (a - \lfloor \frac{x}{y} \rfloor b)y$

Returns $(d, b, (a - \lfloor \frac{x}{y} \rfloor \cdot b))$.
