

# Lecture 1

## OUTLINE

- Basic Semiconductor Physics
  - Semiconductors
  - Intrinsic (undoped) silicon
  - Doping
  - Carrier concentrations

Reading: Chapter 2.1

# What is a Semiconductor?

- Low resistivity => “conductor”
- High resistivity => “insulator”
- Intermediate resistivity => “semiconductor”
  - conductivity lies between that of conductors and insulators
  - generally crystalline in structure for IC devices
    - In recent years, however, non-crystalline semiconductors have become commercially very important

polycrystalline    amorphous    crystalline

# Semiconductor Materials

	III	IV	V	
	Boron (B)	Carbon (C)		
• • •	Aluminum (Al)	Silicon (Si)	Phosphorus (P)	• • •
	Gallium (Ga)	Germanium (Ge)	Arsenic (As)	
		•		
		•		
		•		

# Silicon

- Atomic density:  $5 \times 10^{22}$  atoms/cm<sup>3</sup>
- Si has four valence electrons. Therefore, it can form covalent bonds with four of its nearest neighbors.
- When temperature goes up, electrons can become free to move about the Si lattice.

## Electronic Properties of Si

- **Silicon is a semiconductor material.**
  - Pure Si has a relatively high electrical resistivity at room temperature.
- **There are 2 types of mobile charge-carriers in Si:**
  - Conduction electrons are negatively charged;
  - Holes are positively charged.
- **The concentration (#/cm<sup>3</sup>) of conduction electrons & holes in a semiconductor can be modulated in several ways:**
  1. by adding special impurity atoms (dopants)
  2. by applying an electric field
  3. by changing the temperature
  4. by irradiation

EE105 Spring 2008

Lecture 1, Slide 5

## Electron-Hole Pair Generation

- When a conduction electron is thermally generated, a “hole” is also generated.
- A hole is associated with a positive charge, and is free to move about the Si lattice as well.

EE105 Spring 2008

Lecture 1, Slide 6

## Carrier Concentrations in Intrinsic Si

- The “band-gap energy”  $E_g$  is the amount of energy needed to remove an electron from a covalent bond.
- The concentration of conduction electrons in intrinsic silicon,  $n_i$ , depends exponentially on  $E_g$  and the absolute temperature ( $T$ ):

$$n_i = 5.2 \times 10^{15} T^{3/2} \exp \frac{-E_g}{2kT} \text{ electrons / cm}^3$$

$$n_i \cong 1 \times 10^{10} \text{ electrons / cm}^3 \text{ at } 300\text{K}$$

$$n_i \cong 1 \times 10^{15} \text{ electrons / cm}^3 \text{ at } 600\text{K}$$

EE105 Spring 2008

Lecture 1, Slide 7

## Doping (N type)

- Si can be “doped” with other elements to change its electrical properties.
- For example, if Si is doped with phosphorus (P), each P atom can contribute a conduction electron, so that the Si lattice has more electrons than holes, *i.e.* it becomes “N type”:

**Notation:**

$n$  = conduction electron concentration

EE105 Spring 2008

Lecture 1, Slide 8

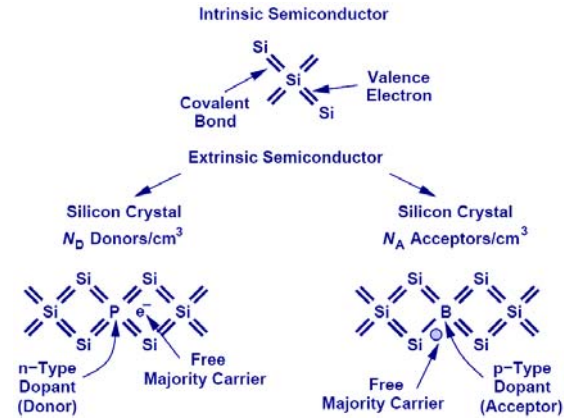

## Doping (P type)

- If Si is doped with Boron (B), each B atom can contribute a hole, so that the Si lattice has more holes than electrons, *i.e.* it becomes "P type":

**Notation:**  
 $p$  = hole concentration

## Summary of Charge Carriers

## Electron and Hole Concentrations

- Under thermal equilibrium conditions, the product of the conduction-electron density and the hole density is ALWAYS equal to the square of  $n_i$ :

$$np = n_i^2$$

- This is called mass-action law

### N-type material

$$n \approx N_D$$

$$p \approx \frac{n_i^2}{N_D}$$

### P-type material

$$p \approx N_A$$

$$n \approx \frac{n_i^2}{N_A}$$

## Terminology

donor: impurity atom that increases  $n$

acceptor: impurity atom that increases  $p$

N-type material: contains more electrons than holes

P-type material: contains more holes than electrons

majority carrier: the most abundant carrier

minority carrier: the least abundant carrier

intrinsic semiconductor:  $n = p = n_i$

extrinsic semiconductor: doped semiconductor

## Summary

---

- The band gap energy is the energy required to free an electron from a covalent bond.
  - $E_g$  for Si at 300K = 1.12eV
- In a pure Si crystal, conduction electrons and holes are formed in pairs.
  - Holes can be considered as positively charged mobile particles which exist inside a semiconductor.
  - Both holes and electrons can conduct current.
- Substitutional dopants in Si:
  - Group-V elements (**donors**) contribute conduction electrons
  - Group-III elements (**acceptors**) contribute holes
  - Very low ionization energies (<50 meV)
