DFT and Sampling the DTFT

Circular Convolution as Matrix Operation

Circular convolution:

- H_c is a circulant matrix
- The columns of the DFT matrix are Eigen vectors of circulant matrices.
- Eigen vectors are DFT coefficients. How can you show?

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Circular Convolution as Matrix Operation

Diagonalize:

$$W_{N}H_{c}W_{n}^{-1} = \begin{bmatrix} H[0] & 0 \cdots & 0 \\ 0 & H[1] \cdots & 0 \\ \vdots & 0 & H[N-1] \end{bmatrix}$$

• Right-multiply by W_N

$$W_{N}H_{c} = \begin{bmatrix} H[0] & 0 \cdots & 0 \\ 0 & H[1] \cdots & 0 \\ \vdots & 0 & H[N-1] \end{bmatrix} W_{N}$$

• Multiply both sides by x

$$W_{N}H_{c}x = \begin{bmatrix} H[0] & 0 \cdots & 0 \\ 0 & H[1] \cdots & 0 \\ \vdots & 0 & H[N-1] \end{bmatrix} W_{N}x$$

Fast Fourier Transform Algorithms

• We are interested in efficient computing methods for the DFT and inverse DFT:

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{kn}, \quad k = 0, \dots, N-1$$
$$x[n] = \sum_{k=0}^{N-1} X[k] W_N^{-kn}, \quad n = 0, \dots, N-1$$

where

$$W_N = e^{-j\left(\frac{2\pi}{N}\right)}.$$

• Fast Fourier transform algorithms enable computation of an

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

• Recall that we can use the DFT to compute the inverse DFT:

$$\mathcal{DFT}^{-1}{X[k]} = \frac{1}{N} \left(\mathcal{DFT}{X^{*}[k]}\right)^{n}$$

Hence, we can just focus on efficient computation of the DFT.

• Straightforward computation of an *N*-point DFT (or inverse DFT) requires *N*² complex multiplications.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

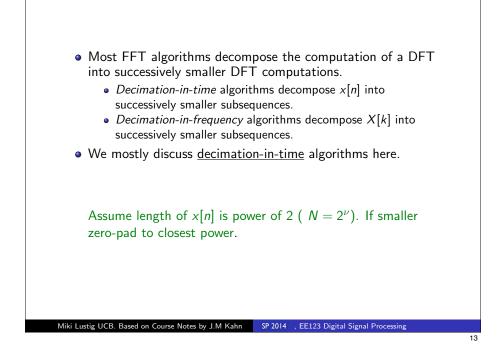

- Most FFT algorithms exploit the following properties of W_N^{kn} :
 - Conjugate Symmetry

$$W_N^{k(N-n)} = W_N^{-kn} = (W_N^{kn})^*$$

• Periodicity in *n* and *k*:

$$W_N^{kn} = W_N^{k(n+N)} = W_N^{(k+N)n}$$

Power:

Let n = 2r (n even) and n = 2r + 1 (n odd):

$$X[k] = \sum_{r=0}^{(N/2)-1} x[2r] W_N^{2rk} + \sum_{r=0}^{(N/2)-1} x[2r+1] W_N^{(2r+1)k}$$
$$= \sum_{r=0}^{(N/2)-1} x[2r] W_N^{2rk} + W_N^k \sum_{r=0}^{(N/2)-1} x[2r+1] W_N^{2rk}$$

• Note that:

$$W_N^{2rk} = e^{-j\left(\frac{2\pi}{N}\right)(2rk)} = e^{-j\left(\frac{2\pi}{N/2}\right)rk} = W_{N/2}^{rk}$$

Remember this trick, it will turn up often.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Decimation-in-Time Fast Fourier Transform

• We start with the DFT

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{kn}, \quad k = 0, \dots, N-1$$

• Separate the sum into even and odd terms:

$$X[k] = \sum_{n \text{ even}} x[n] W_N^{kn} + \sum_{n \text{ odd}} x[n] W_N^{kn}$$

These are two DFT's, each with half of the samples.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

14

Decimation-in-Time Fast Fourier Transform

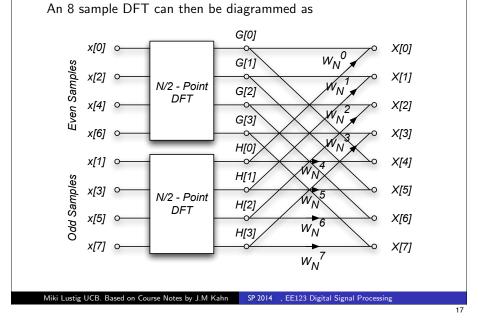

Hence:

$$X[k] = \sum_{r=0}^{(N/2)-1} x[2r] W_{N/2}^{rk} + W_N^k \sum_{r=0}^{(N/2)-1} x[2r+1] W_{N/2}^{rk}$$

$$\stackrel{\Delta}{=} G[k] + W_N^k H[k], \quad k = 0, \dots, N-1$$

where we have defined:

$$G[k] \triangleq \sum_{r=0}^{(N/2)-1} x[2r] W_{N/2}^{rk} \Rightarrow \text{DFT of even idx}$$
$$H[k] \triangleq \sum_{r=0}^{(N/2)-1} x[2r+1] W_{N/2}^{rk} \Rightarrow \text{DFT of odd idx}$$

Decimation-in-Time Fast Fourier Transform The periodicity of *G*[*k*] and *H*[*k*] allows us to further simplify. For the first *N*/2 points we calculate *G*[*k*] and *W^k_NH*[*k*], and then compute the sum *X*[*k*] = *G*[*k*] + *W^k_NH*[*k*] \(\forall \{k : 0 \leq k < \forall \forall \{2\}\}\). How does periodicity help for \(\forall \forall \leq k < N\)?

Decimation-in-Time Fast Fourier Transform

• Both *G*[*k*] and *H*[*k*] are periodic, with period *N*/2. For example

$$G[k + N/2] = \sum_{r=0}^{(N/2)-1} x[2r] W_{N/2}^{r(k+N/2)}$$

$$= \sum_{r=0}^{(N/2)-1} x[2r] W_{N/2}^{rk} W_{N/2}^{r(N/2)}$$

$$= \sum_{r=0}^{(N/2)-1} x[2r] W_{N/2}^{rk}$$

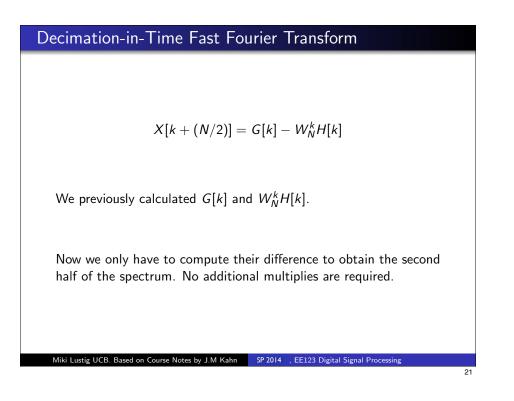

$$= G[k]$$

So
$$G[k + (N/2)] = G[k]$$

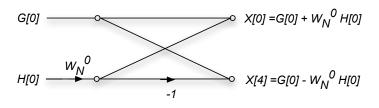

$$H[k + (N/2)] = H[k]$$

Miki Lustig UCB. Based on Course Notes by J.M. Kam
So 2014 _ EE123 Digital Signal Processing

Decimation-in-Time Fast Fourier Transform $X[k] = G[k] + W_N^k H[k] \qquad \forall \{k : 0 \le k < \frac{N}{2} \}.$ • for $\frac{N}{2} \le k < N$: $W_N^{k+(N/2)} = ?$ X[k + (N/2)] = ?

- Note that the inputs have been reordered so that the outputs come out in their proper sequence.
- We can define a *butterfly operation*, e.g., the computation of X[0] and X[4] from G[0] and H[0]:

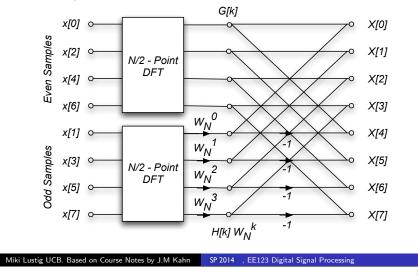

23

This is an important operation in DSP.

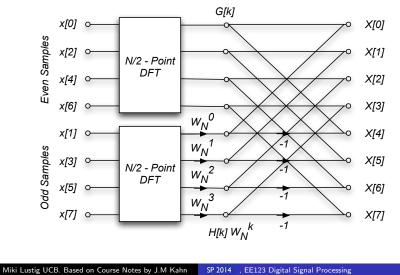

Decimation-in-Time Fast Fourier Transform

• The *N*-point DFT has been reduced two *N*/2-point DFTs, plus *N*/2 complex multiplications. The 8 sample DFT is then:

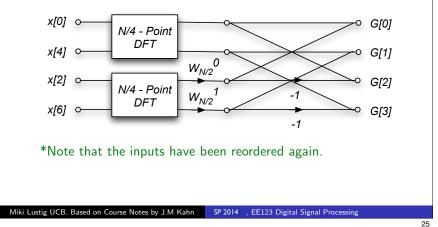

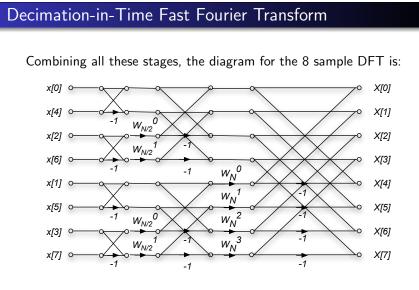

Decimation-in-Time Fast Fourier Transform

• We can use the same approach for each of the N/2 point DFT's. For the N = 8 case, the N/2 DFTs look like

This the decimation-in-time FFT algorithm.

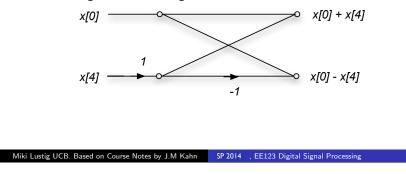

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Decimation-in-Time Fast Fourier Transform

• At this point for the 8 sample DFT, we can replace the N/4 = 2 sample DFT's with a single butterfly. The coefficient is

$$W_{N/4} = W_{8/4} = W_2 = e^{-j\pi} = -1$$

The diagram of this stage is then

Decimation-in-Time Fast Fourier Transform

- In general, there are $\log_2 N$ stages of decimation-in-time.
- Each stage requires N/2 complex multiplications, some of which are trivial.
- The total number of complex multiplications is $(N/2) \log_2 N$.
- The order of the input to the decimation-in-time FFT algorithm must be permuted.
 - First stage: split into odd and even. Zero low-order bit first
 - Next stage repeats with next zero-lower bit first.
 - Net effect is reversing the bit order of indexes

This is illustrated in the following table for N = 8.

Decimal	Binary	Bit-Reversed Binary	Bit-Reversed Decimal
0	000	000	0
1	001	100	4
2	010	010	2
3	011	110	6
4	100	001	1
5	101	101	5
6	110	011	3
7	111	111	7

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Decimation-in-Frequency Fast Fourier Transform		
But $W_N^{2r(n+N/2)} = W_N^{2rn} W_N^N = W_N^{2rn} = W_{N/2}^{rn}$. We can then write		
$X[2r] = \sum_{n=0}^{(N/2)-1} x[n] W_N^{2rn} + \sum_{n=0}^{(N/2)-1} x[n+N/2] W_N^{2r(n+N/2)}$		
$= \sum_{n=0}^{(N/2)-1} x[n] W_N^{2rn} + \sum_{n=0}^{(N/2)-1} x[n+N/2] W_N^{2rn}$		
$= \sum_{n=0}^{(N/2)-1} (x[n] + x[n+N/2]) W_{N/2}^{m}$		

This is the N/2-length DFT of first and second half of x[n] summed.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Decimation-in-Frequency Fast Fourier Transform

The DFT is

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{nk}$$

If we only look at the even samples of X[k], we can write k = 2r,

$$X[2r] = \sum_{n=0}^{N-1} x[n] W_N^{n(2r)}$$

We split this into two sums, one over the first N/2 samples, and the second of the last N/2 samples.

$$X[2r] = \sum_{n=0}^{(N/2)-1} x[n] W_N^{2rn} + \sum_{n=0}^{(N/2)-1} x[n+N/2] W_N^{2r(n+N/2)}$$

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

30

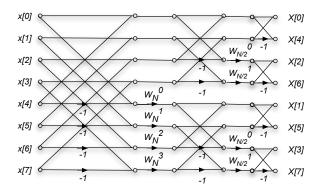

Decimation-in-Frequency Fast Fourier Transform $X[2r] = DFT_{\frac{N}{2}} \{(x[n] + x[n + N/2])\}$ $X[2r + 1] = DFT_{\frac{N}{2}} \{(x[n] - x[n + N/2]) W_N^n\}$ (By a similar argument that gives the odd samples) Continue the same approach is applied for the N/2 DFTs, and the N/4 DFT's until we reach simple butterflies.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

29

Decimation-in-Frequency Fast Fourier Transform

The diagram for and 8-point decimation-in-frequency DFT is as follows

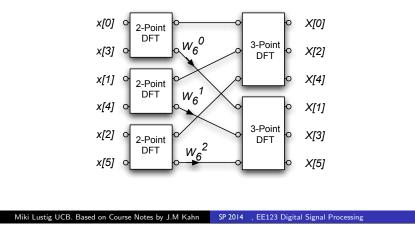

This is just the decimation-in-time algorithm reversed! The inputs are in normal order, and the outputs are bit reversed.

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing

Non-Power-of-2 FFT's

A similar argument applies for any length DFT, where the length N is a composite number.

For example, if N = 6, a decimation-in-time FFT could compute three 2-point DFT's followed by two 3-point DFT's

Non-Power-of-2 FFT's

Good component DFT's are available for lengths up to 20 or so. Many of these exploit the structure for that specific length. For example, a factor of

$$\mathcal{N}_{N}^{N/4} = e^{-j\frac{2\pi}{N}(N/4)} = e^{-j\frac{\pi}{2}} = -j$$
 Why?

just swaps the real and imaginary components of a complex number, and doesn't actually require any multiplies. Hence a DFT of length 4 doesn't require any complex multiplies. Half of the multiplies of an 8-point DFT also don't require multiplication.

Composite length FFT's can be very efficient for any length that factors into terms of this order.

For example N = 693 factors into

$$N = (7)(9)(11)$$

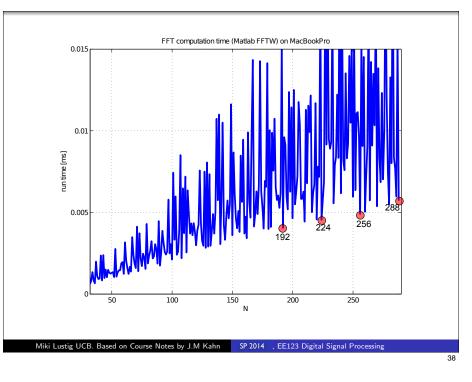

each of which can be implemented efficiently. We would perform

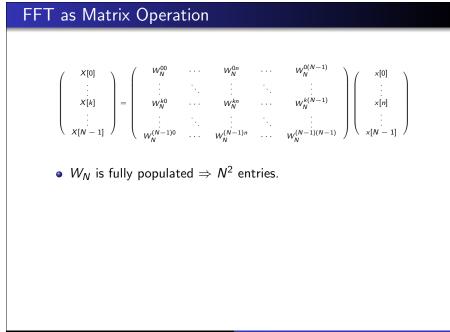

- 9×11 DFT's of length 7
- $\bullet~7\times11$ DFT's of length 9, and
- 7×9 DFT's of length 11

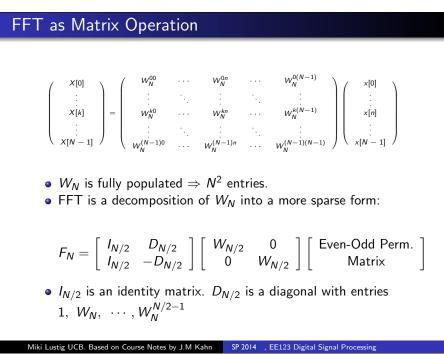

33

- Historically, the power-of-two FFTs were much faster (better written and implemented).
- For non-power-of-two length, it was faster to zero pad to power of two.
- Recently this has changed. The free FFTW package implements very efficient algorithms for almost any filter length. Matlab has used FFTW since version 6

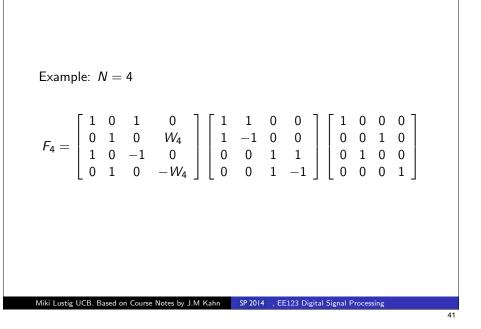

Miki Lustig UCB. Based on Course Notes by J.M Kahn SP 2014 , EE123 Digital Signal Processing
